A Table of Areas Under Disease Progress Curves

Dennis A. Johnson and Roy D. Wilcoxson

Introduction

Disease progress curves illustrate epidemics and reflect the effects of the several factors that influence the development of disease. With appropriately planned experiments disease progress curves may be used to compare the effects of cultivars, races of the pathogens, or individual environmental factors by means of probits, infection rates, slopes, areas under the curves, and perhaps with other procedures (9). The purpose of this bulletin is to provide tables of areas under disease progress curves (AUDPC) when the disease progress curves were constructed from different numbers of observations of epidemics at different time intervals. We have also included some examples from our own studies to demonstrate how the values from the AUDPC tables might be employed in a practical manner.

The area under the disease progress curve (AUDPC) has been used: A. To present the development of plant disease epidemics; B. To indicate the slow rusting characteristics or other types of resistance of cultivars infected with various fungi; and C. To study the sporulation of pathogenic fungi in the field. Since AUDPC indicates in a single statistic both the severity of disease, or the abundance of the pathogen, and the rate at which the disease or pathogen increased during the crop season, it should find wide application in plant disease studies.

AUDPC was first used in 1963 by Vanderplank (24) to study losses in yield due to wheat stem rust and has been used in similar studies by Buchenau (2), Schneider, et al., (16), Singleton (21), Romig and Calpouzos (15) and Johnson and Wilcoxson (7). The value of AUDPC in yield loss models has recently been reviewed by Calpouzos et al. (3) and by James and Teng (6). AUDPC has been used to evaluate the slow rusting characteristics of spring wheats and barley infected with several different rust fungi (5, 8, 10, 13, 14, 22). It has also been used to study the inheritance of slow rusting in wheat infected with the stem rust (22) and leaf rust (5) pathogens and in barley infected with the leaf rust pathogen (8). In addition, it has been used in studies on the stability of slow rusting in wheat infected with stem rust (23, 25, 26). AUDPC was used to study the relationship between the morphological characteristics of wheat peduncles and slow rusting of wheat infected with stem rust (11). Area under the curve was used by Shearer and Wilcoxson (18, 19, 20) to summarize data on the sporulation of *Septoria* species in spring and winter wheats and rye and in spring barley.

Despite the fact the AUDPC has been used in several different kinds of studies, its use has not been widely accepted. The difficulty encountered in constructing disease progress curves and calculating the area under these curves may discourage some research workers from using this method of characterizing plant response to disease. AUDPC can be calculated with the aid of computer programs, but some may not be familiar with or have access to a computer or the program. Others may feel they have too few data to warrant the use of computer facilities.

The computer program used for calculating the values of AUDPC shown in this bulletin was selected and checked for accuracy by Shearer (17). The calculation of AUDPC is given by the formula:

$$\text{area} = \int_{t_1}^{t_h} f(x) dx$$

where t_1 = first sampling date

t_h = last sampling late

$f(x)$ = function describing change of disease with time.

Since $f(x)$ is often not known, AUDPC may be estimated by summing weighted datum observations with the aid of Fortran IV subroutine AREA and the subroutine INVERT of Davies (4). Details on how AREA calculates the areas is given in Bevington (1).

How to Use the Tables

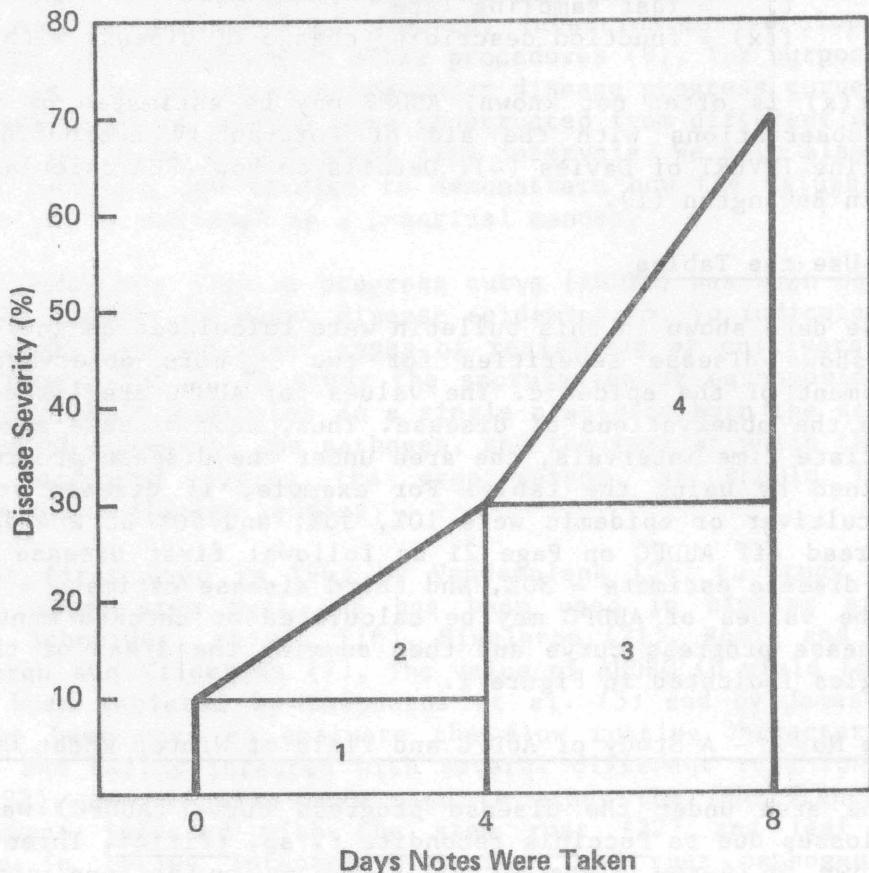

The data shown in this bulletin were calculated as indicated above. The table shows disease severities for two or more observations during the development of the epidemic. The values for AUDPC are listed under the days between the observations of disease. Thus, from disease severities taken at appropriate time intervals, the area under the disease progress curve can be determined by using the table. For example, if disease severities for a given cultivar or epidemic were 10%, 30%, and 70% at a 4-day interval, one would read off AUDPC on Page 21 as follows: first disease estimate = 10%, second disease estimate = 30%, and third disease estimate = 70%, and AUDPC = 280. The values of AUDPC may be calculated or checked manually by drawing the disease progress curve and then summing the areas of the triangles and rectangles indicated in Figure 1.

Example No. 1 - A Study of AUDPC and Yield of Winter Wheat Cultivars

The area under the disease progress curve (AUDPC) was used to study yield losses due to Puccinia recondita f. sp. tritici. Three wheat cultivars were sown in 4-row plots 12 ft. long on an Abilene clay loam soil at Chillicothe, TX. Plots were in a split plot design of 10 replicates. The two border rows of the main plots were inoculated with an oil suspension of urediospores of Puccinia recondita f. sp. tritici (Avirulent/Virulent formula: LR 2A, 2D, 16, 17, 19/LRI, 3, 3B, 9, 10, 11, 18) or the main plots were kept disease-free by spraying plots with Dithane M-45. The subplots were the cultivars. Fungicide spraying began 10 days after inoculation and was continued once a week.

About three weeks after inoculation, rust had developed sufficiently in the two center rows of the inoculated plots to begin a systematic assessment of leaf rust development by estimating leaf rust severity with the modified Cobb's scale (12) at 10 day intervals. The growth stage of the cultivars was recorded using the Romig scale (3). At the end of the epidemic, AUDPC was determined from the Table in this bulletin. Rust did not noticeably increase after the fourth disease severity reading (early dough stage of growth) because of hot and dry weather. The grain ripened soon afterwards and the fourth disease severity reading was the last reading used in determining AUDPC.

Fig. 1 Example of Manual Calculation of Area Under the Disease Progress Curve (AUDPC).

Rectangle or Triangle	Area
1 (4 x 10)	= 40
2 (4 x 20/2)	= 40
3 (4 x 30)	= 120
4 (4 x 40/2)	= 80
AUDPC	= 280

The grain from the two center rows of each plot was harvested when ripe. The yield ratio: weight of yield of disease plot/mean weight of yield of disease-free plots, and the 1000 kernel weight ratio: weight of 1000 kernels of diseased plot/mean weight of 1000 kernels of disease-free plots, were calculated.

The disease progress curves and the growth stage of the cultivars during the epidemic are shown in Figure 2. AUDPC, yield ratio, and 1000 kernel weight ratio of each cultivar are listed in Table 1. Differences among the cultivars were all significant ($P = 0.05$).

TAM W-101 rusted more slowly than Newton. The low AUDPC value of Blueboy II can not be attributable to slow rusting, but to race specific resistance to leaf rust races prevalent during the beginning of the epidemic. A race virulent on Blueboy II infected the plants during the latter part of the epidemic (Figure 2).

Table 1. Mean Area under the Disease Progress Curve, Yield Ratio and 1000-Kernel Weight Ratio of Three Winter Wheat Cultivars Infected with *Puccinia recondita* f. sp. *tritici*.

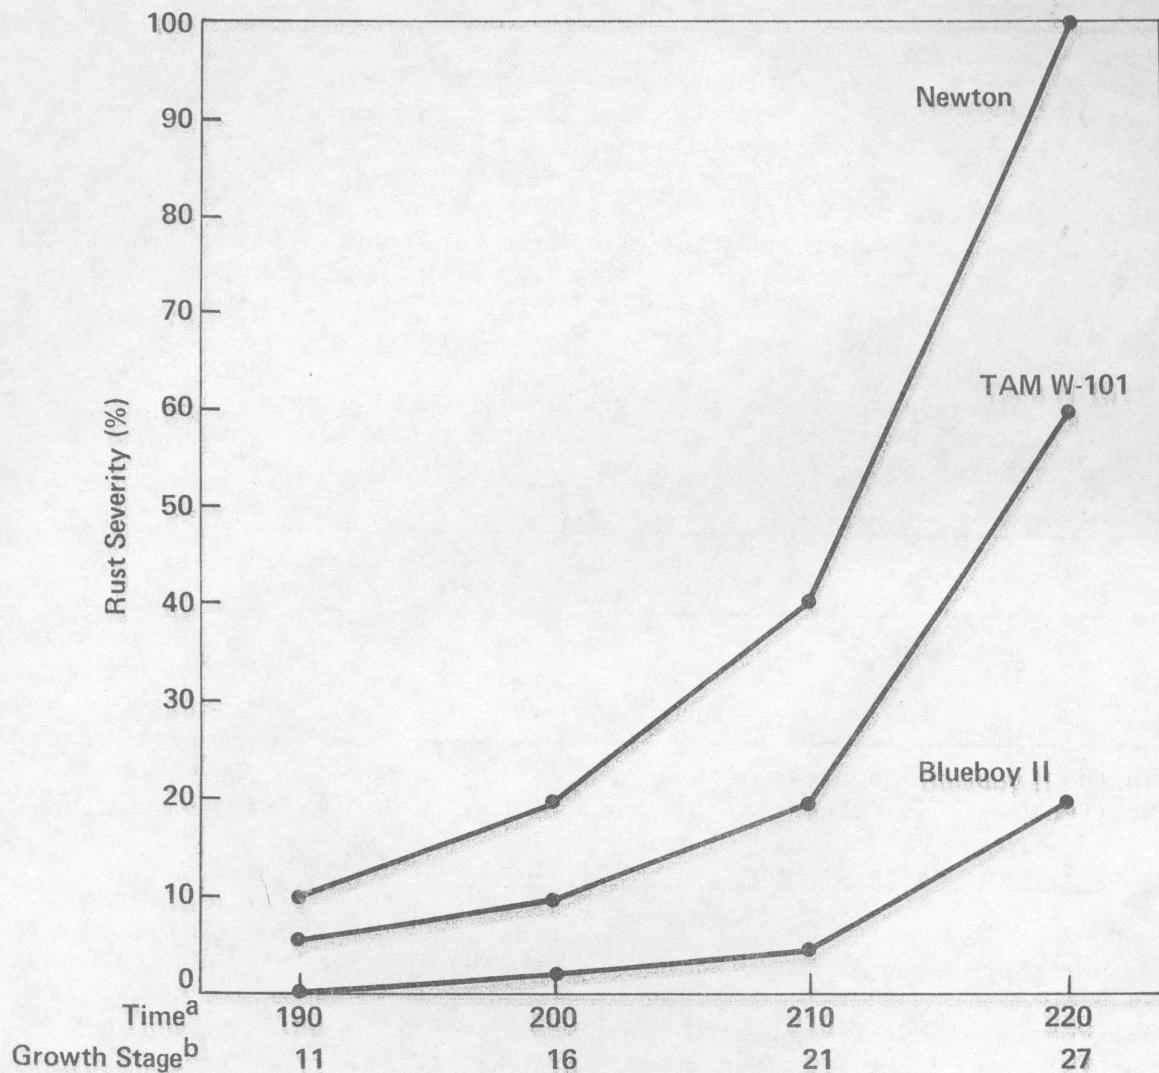

Cultivar	Area	Yield Ratio	Kernel Wt. Ratio
Newton	1150 a	.695 c	.882 c
TAM W-101	625 b	.886 b	.921 b
Blueboy II	160 c	.997 a	.959 a

Values in the same column not followed by the same letter are significantly different ($P = 0.05$) as determined by Duncan's multiple range test.

Example No. 2. Evaluation of AUDPC of Spring Wheat Cultivars

AUDPC was used to evaluate the slow rusting characteristic of three cultivars of spring wheat in a fertilizer experiment at Rosemount, MN, in 1979. The experiment was located in a field that had been used for a fertilizer factorial experiment each year since 1959. The plots were 7.7 X 19 m in size and there were four replicates with the fertilizers being the main plots and the cultivars the sub plots. In the spring, 363 kg of NH_4NO_3 , 312 kg of P_2O_5 , and 335 kg of K_2O were scattered by hand on the appropriate plots and then the field was disced and planted. The spring wheat (*Triticum aestivium* L.) cultivars Lee, Marquis, and Thatcher were each planted at the rate of 90 kg of seed per hectare as a strip 2.4 m wide in each fertilizer plot during the first week of May. The cultivars were chosen because Lee was known to rust at a moderate rate with stem rust, Marquis to rust rapidly, and Thatcher to rust slowly. Leaf rust (*Puccinia recondita* f. sp. *tritici*) was prevented from developing in the plots by spraying with triazbutil (4-butyl-4H-1,2,4-triazole) (Indar^R, Rohm and Haas Co., Philadelphia, PA 19105) at the rate of 877 ml/ha when plants were 2 weeks old. When plants were in the early boot growth stage, they were inoculated with freshly collected urediospores of *Puccinia graminis* f. sp. *tritici* race 15B2-TLM suspended in Soltrol. Stem rust severity was evaluated once weekly beginning about one week before inoculation and then for four weeks after inoculation with the aid of the modified Cobb Scale (12). The rust severity data were converted

Fig. 2 Disease Progress Curves of Three Winter Wheat Cultivars Infected with *Puccinia recondita* f. sp. *tritici*.

^aDays from planting

^bRomig Scale:

16 = Beginning of flowering

21 = Kernels near middle of head $\frac{1}{2}$ formed

27 = Early dough

to AUDPC from the table in this bulletin. Analysis of variance was used to help interpret AUDPC values in the various treatments.

Stem rust was severe in the fertility plots (Figure 3). In each fertilizer treatment Thatcher rusted slowly, Lee at a moderate rate, and Marquis rapidly (Table 3). These rusting characteristics of the cultivars were readily identified and agreed with previous reports. Of the fertilizer treatments, only nitrogen (NH_4NO_3) significantly affected stem rust development ($P = .05$); it increased the average value of AUDPC from 588 in plots that were not fertilized with NH_4NO_3 to 645 in plots that were fertilized.

Table 2. Mean Area under the Disease Progress Curve When Three Spring Wheat Cultivars Were Grown in Fertilizer Plots and Infected with *Puccinia graminis* f. sp. *tritici*.

Fertilizer ^{a/}	Areas/Cultivar ^{b/}		
	<u>Thatcher</u>	<u>Lee</u>	<u>Marquis</u>
N	342	687	910
P	265	653	892
K	258	705	884
NP	387	705	954
NK	366	684	901
PK	314	600	875
NPK	356	579	875
None	278	622	831
Average	321	640	890

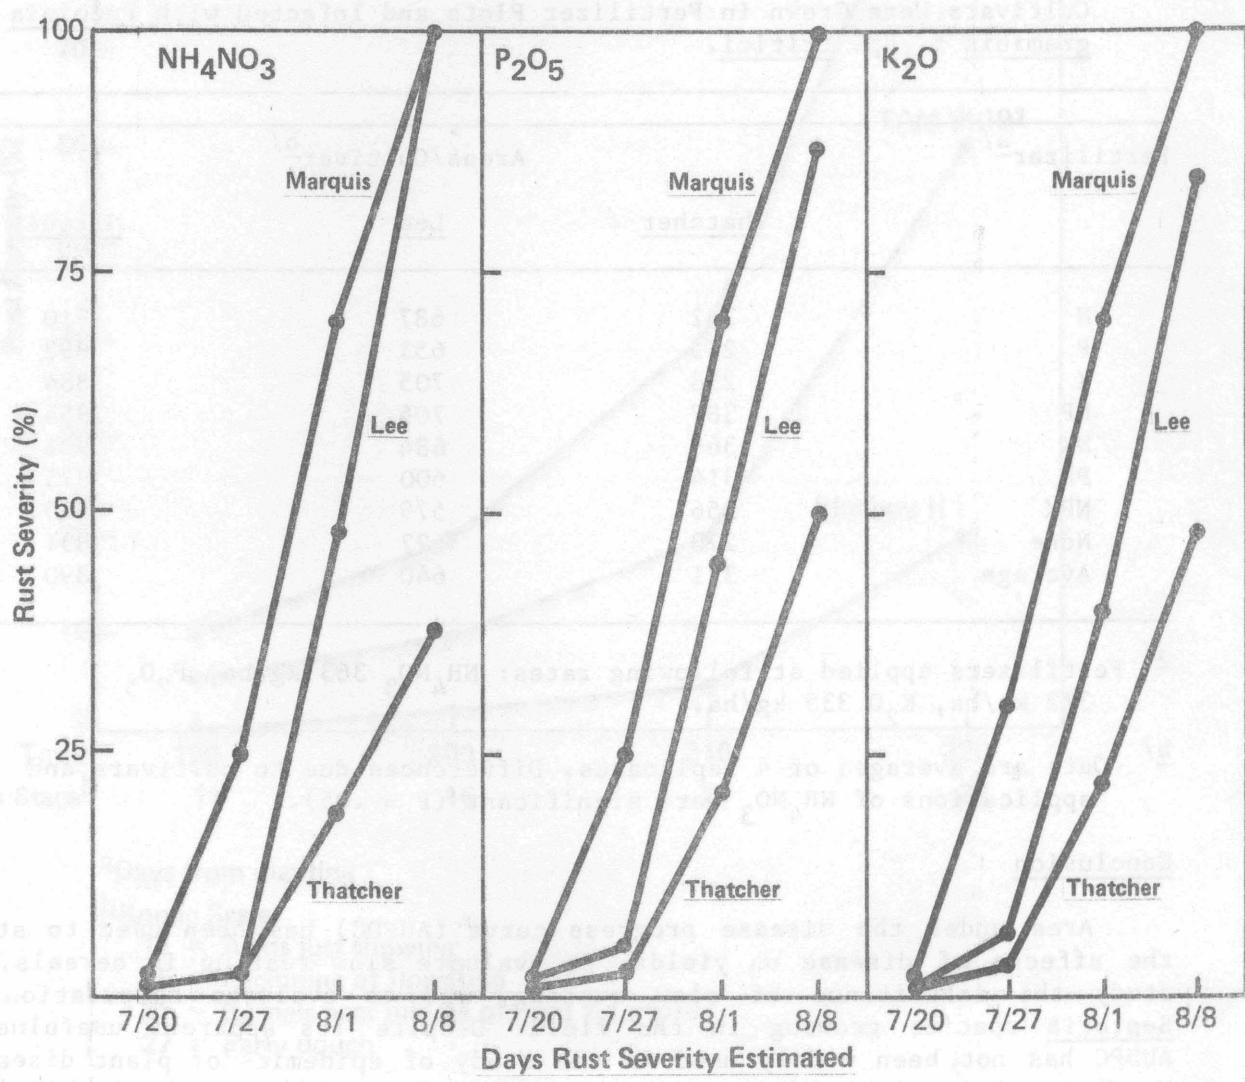

^{a/} Fertilizers applied at following rates: NH_4NO_3 363 kg/ha, P_2O_5 312 kg/ha, K_2O 335 kg/ha.

^{b/} Data are averages of 4 replicates. Differences due to cultivars and applications of NH_4NO_3 were significant ($P = .05$).

Conclusion

Area under the disease progress curve (AUPDC) has been used to study the effects of disease on yields, to evaluate slow rusting in cereals, to study the inheritance of slow rusting, and to evaluate sporulation of *Septoria* species growing in the field. Despite its apparent usefulness, AUDPC has not been widely used in the study of epidemics of plant disease. We hope that the tables in this bulletin that provide AUDPC for many different epidemics will facilitate a greater use of this useful statistic.
