ABSTRACT

Rate Transient Analysis in Shale Gas Reservoirs with Transient Linear Behavior.

(May 2009)

Rasheed Olusehun Bello, B.Sc., University of Lagos, Nigeria;
M.Sc., University of Saskatchewan, Canada

Chair of Advisory Committee: Dr. Robert Wattenbarger

Many hydraulically fractured shale gas horizontal wells in the Barnett shale have been observed to exhibit transient linear behavior. This transient linear behavior is characterized by a one-half slope on a log-log plot of rate against time. This transient linear flow regime is believed to be caused by transient drainage of low permeability matrix blocks into adjoining fractures. This transient flow regime is the only flow regime available for analysis in many wells.

The hydraulically fractured shale gas reservoir system was described in this work by a linear dual porosity model. This consisted of a bounded rectangular reservoir with slab matrix blocks draining into adjoining fractures and subsequently to a horizontal well in the centre. The horizontal well fully penetrates the rectangular reservoir. Convergence skin is incorporated into the linear model to account for the presence of the horizontal wellbore.

Five flow regions were identified with this model. Region 1 is due to transient flow only in the fractures. Region 2 is bilinear flow and occurs when the matrix drainage begins simultaneously with the transient flow in the fractures. Region 3 is the response
for a homogeneous reservoir. Region 4 is dominated by transient matrix drainage and is
the transient flow regime of interest. Region 5 is the boundary dominated transient
response. New working equations were developed and presented for analysis of Regions
1 to 4. No equation was presented for Region 5 as it requires a combination of material
balance and productivity index equations beyond the scope of this work.

It is concluded that the transient linear region observed in field data occurs in
Region 4 – drainage of the matrix. A procedure is presented for analysis. The only
parameter that can be determined with available data is the matrix drainage area, \( A_{cm} \).

It was also demonstrated in this work that the effect of skin under constant rate
and constant bottomhole pressure conditions is not similar for a linear reservoir. The
constant rate case is the usual parallel lines with an offset but the constant bottomhole
pressure shows a gradual diminishing effect of skin. A new analytical equation was
presented to describe the constant bottomhole pressure effect of skin in a linear
reservoir.

It was also demonstrated that different shape factor formulations (Warren and
Root, Zimmerman and Kazemi) result in similar Region 4 transient linear response
provided that the appropriate \( f(s) \) modifications consistent with \( \lambda_{Ac} \) calculations are
conducted. It was also demonstrated that different matrix geometry exhibit the same
Region 4 transient linear response when the area-volume ratios are similar.
DEDICATION

I dedicate my work to all those who have lovingly supported me throughout life and all its travails.
ACKNOWLEDGEMENTS

First, I want to give praises to Almighty Allah for sparing my life, continuously granting me His blessings and allowing me to successfully conclude this phase of my life.

I want to acknowledge my supervisor, Dr. Robert. A. Wattenbarger for being a father, mentor, supervisor and friend to me. I am honored to have worked with him. I am also eternally grateful to him. I want to acknowledge the suggestions and contributions of my committee members, Dr. Christine Ehlig-Economides , Dr. Bryan Maggard – whose classes are among my favorites and invaluable- and Dr. Goong Chen.

I want to acknowledge the eternal support of my parents, Rahaman and Doja Bello, my siblings- Biodun, Bidemi and Tolu- and my girl, Medinat.

CHAPTER I
INTRODUCTION

Natural gas demand in the United States is expected to increase from 23 tcf/yr currently to 30-34 tcf/yr by the year 2025.\(^1\) United States natural gas production is also expected to increase from 19.5 tcf/yr in 2004 to more than 25 tcf/yr by the year 2020 in order to satisfy this demand as shown in Fig. 1.1. Conventional gas sources (sandstone reservoirs) will not be able to satisfy this demand and unconventional gas sources (tight gas, shale gas and coalbed methane) are thus expected to be a major component of this production (Fig. 1.1).

Unconventional reservoirs are defined as reservoirs that cannot be produced at economic flowrates or that do not produce economic volumes of oil and gas without assistance from massive stimulation treatments or special recovery processes, such as steam injection.\(^2\) Unconventional reservoirs are normally described as basin-centered continuous accumulations. The hydrocarbons are distributed throughout a large area. These accumulations do not have well-defined hydrocarbon-water contacts and are usually abnormally pressured.\(^3\)

Shales are fissile rocks composed of layers of fine-grained sediments. Shale reservoirs are normally regarded as the source rocks for the petroleum system according

\(^{1}\) This dissertation follows the style of Society of Petroleum Engineers Journal.
to the organic theory. The hydrocarbon is generated in the source rock (shale) and migrates to a reservoir rock (e.g. sandstone). However, the unconventional shale gas reservoir which is the focus of this study are self-sourcing reservoirs. The shale acts as both a source rock and reservoir.

A map of the major shale basins in the United States is shown in Fig. 1.2. The Gas Technology Institute estimates that organic shale reservoirs in the United States contain up to 780 tcf of gas. The Barnett Shale in the Fort Worth Basin is by far the most active shale gas play in the United States. The reservoir ranges from 100 ft to more than 1000 ft in gross thickness and holds from 50 to 200 bcf of gas per square mile.\footnote{Projections: Energy Information Administration, Annual Energy Outlook 2000, DOE/EIA-0383(2000) (Washington, DC, December 1999), reference case.}
Shales can be classified based on hydrocarbon (gas) generation mechanism as thermogenic (organic matter is transformed into hydrocarbons under the influence of temperature) or biogenic (water which contains microorganisms migrates into the rock and transforms the organic matter).

Shales can be also be classified as: (i) Shales having very fine sand and silt laminae and beds; gas is thermogenic (similar to tight sand e.g. Ohio Shale, Lewis shale); (ii) Dark organic-rich shales having water-filled fractures and must be depressurized (like coalbed reservoirs; gas reservoirs may be biogenic or thermogenic e.g. Antrim shale); and (iii) Mixed – Shales that have characteristics of the above, depending on location in basin e.g. New Albany Shale.
In general, shale gas reservoirs are characterized by low production rates (20 to 500 Mcf per day), long production lives (up to 30 yrs), low decline rates (typically 2 to 3% per yr), ability to be thick (up to 1,500 ft) and large gas reserves (5 bcf to 50 bcf per section). Shale gas reservoirs are also typically organically rich.

In shales, natural fractures provide permeability and the matrix provides storage of most of the gas. They are thus also referred to as a Nelson Type II Fractured Reservoir. Shale matrix permeabilities can be as low as $10^{-9}$ md. Matrix porosities range from 1 to 6%. The gas is stored either by compression (as free gas) or by adsorption on the surfaces of the solid material (either organic matter or minerals).

The adsorption (desorption) behavior of shale gas reservoirs have typically been modeled by the Langmuir isotherm. It has been shown that in the Barnett shale, at higher pressures (above 1000 psia), gas storage occurs as free gas in the matrix porosity. Below 1000 psia, desorption is important and adsorbed gas may account for 50 to 60% of total gas stored.

Shale gas reservoirs were traditionally ignored because of the low matrix permeability and the costs thus associated with production. The Section 29 tax credit (1980-2002) was one of the factors which revived interest in these reservoirs. It allowed a credit of $3 per barrel of oil equivalent for production from unconventional sources. It was amended in 2003 by the Energy Policy Act Section 1345. Other factors were technological improvements and include horizontal wells and hydraulic fracturing. The use of water-based or nitrogen foam fracturing fluids along with proppants in hydraulic
fracturing have aided production from these reservoirs. In recent times, high oil and gas prices have renewed interest in shale gas reservoir exploitation.

1.1 Problem Description

Horizontal wells producing gas in the Barnett shale are typically multi-stage hydraulically fractured. Typical micro-seismic data used to monitor the hydraulic fractures is shown in Fig. 1.3. The different hydraulic fracture stages are indicated by the different clusters.

Shale gas production data from a sample well in the Barnett shale is plotted against time on a log-log plot as shown in Fig. 1.4. A half-slope is obtained on the plot. This indicates a transient linear regime analogous to Regime 4 described by Ozkan et al.\textsuperscript{12} for dual porosity behavior in a radial reservoir. The transient linear behavior shown in Fig. 1.4 occurs for a duration of almost two log cycles. The transient linear behavior shown in Fig. 1.4 has been observed in several shale gas wells and is the only flow regime available for analysis in numerous cases. The question thus arises of how to conduct proper analysis of this flow regime and what parameters can be determined.

Wattenbarger\textsuperscript{13} identified different causes for transient linear flow including hydraulic fracture draining a square geometry, high permeability layers draining adjacent tight layers and early-time constant pressure drainage from different matrix geometry. A possible cause for the transient linear regime identified in Fig. 1.4 is the drainage from the matrix blocks into high permeability surrounding fractures (as demonstrated in Appendix A). These high permeability fractures thus have negligible pressure drop and
Fig. 1.3 – Microseismic Map of Multi-Stage Hydraulically Fractured Horizontal Well.

Fig. 1.4 - Log-log Plot of Field Production Rate as a Function of Time. Line drawn on plot indicates half slope.
transient linear flow occurs. This description is consistent with the dual porosity concept for shale gas reservoirs.

Mayerhofer et al.\textsuperscript{14} present a model for hydraulically fractured shale gas reservoirs. Their model represents the hydraulic fracture as an interconnected network of fractures. Their paper indicates that drainage does not occur far beyond the stimulated region because of the low matrix permeability. This observation was also stated by Carlson and Mercer.\textsuperscript{15}

In the current work, the hydraulically fractured horizontal shale gas well will be modeled as a horizontal well draining a rectangular geometry containing a network of fractures separated by matrix blocks (dual-porosity system) as suggested by Fig. 1.3. The solutions presented by El-Banbi\textsuperscript{16} for a linear dual porosity model will be extended and applied to this system. The effects of desorption and diffusion will be assumed negligible in this paper since they will not be important at reservoir pressures of interest in the Barnett shale as previously described.

1.2 Objectives

The objectives of this research are

- To develop mathematical models to analyze these multi-stage hydraulically fractured horizontal wells
- To develop a rate transient analysis procedure for analyzing these wells to enable the determination of reservoir characteristics, drainage
volume/original gas-in-place (OGIP), fracture network characteristics and assessment of the effectiveness of different hydraulic fracture treatments.

1.3 Organization of This Dissertation

The study is divided into eight chapters. The outline and organization of this dissertation are as follows:

Chapter I presents an overview of shale gas. The research problem is described and the project objectives are presented.

Chapter II presents an extensive literature review. The dual porosity model and its applications to liquids and gas are reviewed. Horizontal well applications are also reviewed.

Chapter III describes the linear model to be used in this work. Validation of the linear model is also presented.

Chapter IV presents new analysis equations developed using the linear model.

Chapter V discusses the transient linear regime in detail and discusses the effects of shape factors and area-volume ratio.

Chapter VI describes the constant bottomhole pressure effect of skin in linear reservoirs.

Chapter VII presents development of new type curves with application to sample field data.

Chapter VIII presents conclusions and recommendations.
CHAPTER II
LITERATURE REVIEW

2.1 Introduction

Initial studies of fractured reservoirs were concerned with applications to well test analysis of reservoir flow of liquids (constant rate, pressure buildup and drawdown). Subsequent research considered production data analysis (constant bottomhole pressure) and extension of existing models to gas flow. Most of the literature is devoted to radial reservoir models. In this chapter, review of literature will be conducted in three sections. The first section discusses the dual porosity model and its application to flow of slightly compressible fluids. The second section discusses the application of the dual porosity model to gas flow. The final section discusses the application of the dual porosity model to analysis of naturally fractured reservoirs with horizontal wells.

2.2 Dual Porosity Model (Slightly Compressible Fluids)

Naturally fractured reservoirs (tight gas, shale gas and coal gas) have been described by the dual porosity model. The dual porosity model was first formulated by Barenblatt et al.\textsuperscript{17} and later extended to well test analysis by Warren and Root.\textsuperscript{18} The Warren and Root model forms the basis of modern day analysis of naturally fractured reservoirs. In the Warren and Root model, the naturally fractured reservoir is modeled by uniform homogeneous matrix blocks separated by fractures as shown in Fig. 2.1. The matrix blocks provide storage of the fluid to be produced while the fractures provide the
permeability. When a producing well is present, the fluid flows from the matrix to the fractures and to the well. There have been two types of approach in applying the dual porosity model based on how flow of the fluid from the matrix to the fractures is modeled – pseudosteady state and transient.

**Fig. 2.1 - Dual Porosity Model.**

### 2.2.1 Pseudosteady State Matrix-Fracture Transfer Models

An equation for interporosity flow from the matrix to the fractures at a mathematical point under pseudosteady state (quasisteady state or semisteady state) conditions was presented by Warren and Root.\(^\text{18}\)
\[ q = \sigma \frac{k}{\mu} \left( p_m - p_f \right) \]

Where \( q \) is the drainage rate per unit volume, \( \sigma \) is the Warren and Root shape factor, \( p_m \) is the matrix pressure at a mathematical point.

Two new parameters which are used to characterize naturally fractured reservoirs were presented by Warren and Root\(^{18}\) - the interporosity flow parameter, \( \lambda \) (a measure of the flow capacity of the system) and the storativity, \( \omega \) (a measure of the storage capacity of the fractures). Warren and Root\(^{18}\) were the first to apply Laplace transformation to obtain “\( f(s) \)” and solve for the dimensionless pressure distribution. A method of analyzing pressure buildup data for the infinite radial reservoir case was presented. Buildup plots were found to exhibit parallel lines on a semilog plot separated by an S-shaped transition period. The first line represents flow in the fracture system only while the second line represents flow in the total system (matrix and fractures).

Kazemi \textit{et al.}\(^{19}\) investigated the suitability of applying the Warren and Root model to interpret interference results. They presented a model which extends the Warren and Root model to interference testing. They applied the Laplace transformation to obtain “\( f(s) \)” and solve for the dimensionless pressure distribution. They also numerically solved the model equations by finite-difference methods and included vertical pressure gradients. It was concluded that an equivalent homogeneous model was not appropriate at early times but could be used at later times. It was also concluded that the Warren and Root model yielded similar results as their numerical solution and was thus appropriate for analyzing naturally fractured reservoirs.
Odeh developed an infinite radial reservoir model for the behavior of naturally fractured reservoir. The model incorporates some limiting assumptions. The Laplace transformation is also utilized. Two parallel straight lines were not observed on a semilog plot contrary to Warren and Root’s results. It was concluded that buildup and drawdown plots of naturally fractured reservoir transient responses are similar to those of homogeneous reservoirs.

Mavor and Cinco-Ley present solutions for the constant rate case in an infinite radial reservoir with and without wellbore storage and skin; and a bounded radial reservoir. Solutions are also presented for the first time for a constant pressure inner boundary with skin in an infinite radial reservoir.

Da Prat et al. extended the Warren and Root solutions to constant pressure inner boundary conditions and bounded outer boundary cases for the radial reservoir. They also present type curves for analysis. The results do not appear to represent realistic field cases.

Bui et al. present type curves for transient pressure analysis of partially penetrating wells in naturally fractured reservoirs by combining the Warren and Root model with the solution for these wells in homogeneous reservoirs.

2.2.2 Transient Matrix-Fracture Transfer Models

Kazemi used a slab matrix model with horizontal fractures and unsteady state matrix-fracture flow to represent single-phase flow in the fractured reservoir. The assumptions include homogeneous behavior and isotropic matrix and fracture properties. The well is
centrally located in a bounded radial reservoir. A numerical reservoir simulator was used. It was concluded that the results were similar to the Warren and Root model when applied to a drawdown test in which the boundaries have not been detected. Two parallel straight lines were obtained on a semilog plot. The first straight line may be obscured by wellbore storage effects and the second straight line may lead to overestimating \( \omega \) when boundary effects have been detected.

De Swaan\textsuperscript{25} presented a model which approximates the matrix blocks by regular solids (slab and spheres) and utilizes heat flow theory to describe the pressure distribution. It was assumed that the pressure in the fractures around the matrix blocks is variable and the source term is described through a convolution term. Approximate line-source solutions for early and late time are presented. The late time solutions are similar to those for early time except that modified hydraulic diffusivity terms dependent on fracture and matrix properties are included. The results are two parallel lines representing the early and late time approximations. The late time solution matches Kazemi\textsuperscript{24} for the slab case. De Swaan’s model does not properly represent the transition period.

Najurieta\textsuperscript{26} presented a transient model for analyzing pressure transient data based on De Swaan’s\textsuperscript{25} theory. Two types of fractured reservoir were studied—stratum (slabs) and blocks (approximated by spheres). The model predicted results similar to Kazemi.\textsuperscript{24}

Serra \textit{et al.}\textsuperscript{27} present methods for analyzing pressure transient data. The slab model used is similar to De Swaan\textsuperscript{25} and Najurieta.\textsuperscript{26} The model considers unsteady state
matrix fracture transfer and is for an infinite reservoir. Three flow regimes were identified. Flow Regime 1 and 3 are the Warren and Root\textsuperscript{18} early and late time semilog lines. A new flow Regime 2 was also identified with half the slope of the late time semilog line.

Chen \textit{et al.}\textsuperscript{28} present methods for analyzing drawdown and buildup data for a constant rate producing well centrally located in a closed radial reservoir. The slab model similar to De Swaan\textsuperscript{25} and Kazemi\textsuperscript{24} is used. Five flow regimes are presented. Flow regimes 1, 2 and 3 are associated with an infinite reservoir and are described in Serra \textit{et al.}\textsuperscript{27} Flow regime 1 occurs when there is a transient only in the fracture system. Flow regime 2 occurs when the transient occurs in the matrix and fractures. Flow regime 3 is a combination of transient flow in the fractures and “pseudosteady state” in the matrix. Pseudosteady-state in the matrix occurs when the no-flow boundary represented by the symmetry center line in the matrix affects the response. Two new flow regimes associated with a bounded reservoir are also presented. Flow regime 4 reflects unsteady linear flow in the matrix system and pseudosteady-state in the fractures. Flow Regime 5 occurs when the response is affected by all the boundaries (pseudosteady-state).

Streltsova\textsuperscript{29} applied a “gradient model” (transient matrix-fracture transfer flow) with slab-shaped matrix blocks to an infinite reservoir. The model predicted results which differ from the Warren and Root model in early time but converge to similar values in late time. The model also predicted a linear transitional response on a semi-log plot between the early and late time pressure responses which has a slope equal to half
that of the early and late time lines. This linear transitional response was also shown to differ from the S-shaped inflection predicted by the Warren and Root model.

Cinco Ley and Samaniego\textsuperscript{30} utilize models similar to De Swaan\textsuperscript{25} and Najurieta\textsuperscript{26} and present solutions for slab and sphere matrix cases. They utilize new dimensionless variables – dimensionless matrix hydraulic diffusivity, and dimensionless fracture area. They describe three flow regimes observed on a semilog plot – fracture storage dominated flow, “matrix transient linear” dominated flow and a matrix pseudosteady-state flow. The “matrix transient linear” dominated flow period is observed as a line with one-half the slopes of the other two lines.\textsuperscript{27,29} It should be noted that the “matrix transient linear” period yields a straight line on a semilog plot indicating radial flow and might be a misnomer. The fracture storage dominated flow is due to fluid expansion in the fractures. The “matrix transient linear” period is due to fluid expansion in the matrix. The matrix pseudosteady-state period occurs when the matrix is under pseudosteady-state flow and the reservoir pressure is dominated by the total storativity of the system (matrix + fractures). It was concluded that matrix geometry might be identified with their methods provided the pressure data is smooth.

Lai \textit{et al.}\textsuperscript{31} utilize a one-sixth of a cube matrix geometry transient model to develop well test equations for finite and infinite cases including wellbore storage and skin. Their model was verified with a numerical simulator employing the Multiple Interacting Continua (MINC) method.

Ozkan \textit{et al.}\textsuperscript{12} present analysis of flow regimes associated with flow of a well at constant pressure in a closed radial reservoir. The rectangular slab model similar to De
Swaan and Kazemi is used. Five flow regimes are presented. Flow regimes 1, 2 and 3 are described in Serra et al. Two new regimes are presented- Flow regime 4 reflects unsteady linear flow in the matrix system and occurs when the outer boundary influences the well response and the matrix boundary has no influence. Flow Regime 5 occurs when the response is affected by all the boundaries.

Houze et al. present type curves for analysis of pressure transient response in an infinite naturally fractured reservoir with an infinite conductivity vertical fracture.

Stewart and Ascharsobbi present an equation for interporosity skin which can be introduced into the pseudosteadystate and transient models. The effect of interporosity skin is to delay flow from the matrix to the fractures. This equation is given by

\[ s_{ma} = \frac{2k_{mi}h_s}{h_mk_s} \]

where \( k_{mi} \) is the intrinsic matrix permeability, \( h_s \) is the thickness of the interporosity skin layer, \( h_m \) is the matrix block dimension and \( k_s \) is the permeability of the interporosity skin layer.

It should be noted that all the transient models previously described were developed for the radial reservoir cases (infinite or bounded).

El-Banbi was the first to present transient dual porosity solutions for the linear reservoir case. New solutions were presented for a naturally fractured reservoir using a dual porosity, linear reservoir model. Solutions are presented for a combination of different inner boundary (constant pressure, constant rate, with or without skin and
wellbore storage) and outer boundary conditions (infinite, closed, constant pressure). This model will be used in this work.

### 2.3 Dual Porosity Model (Gas)

Kucuk and Sawyer\textsuperscript{34,35} presented a model for transient matrix-fracture transfer for the gas case. Previous work had been concerned mainly with modeling slightly compressible (liquid) flow. They considered cylindrical and spherical matrix blocks cases. They also incorporate the pseudopressure definitions for gases. Techniques for analyzing buildup data are also presented for shale gas reservoirs. Their model results plotted on a dimensionless basis matched Warren and Root\textsuperscript{18} and Kazemi\textsuperscript{24} for very large matrix blocks at early time but differ at later times. They also conclude from their tests that naturally fractured reservoirs do not always exhibit the Warren and Root behavior (two parallel lines).

Carlson and Mercer\textsuperscript{15} coupled Fick’s law for diffusion within the matrix and desorption in their transient radial reservoir model for shale gas. Modifications include use of the pressure-squared forms valid for gas at low pressures to linearize the diffusivity equation. They provide a Laplace space equation for the gas cumulative production from their model and use it to history match a sample well. They also show that semi-infinite behavior (portions of the matrix remain at initial pressure and is unaffected by production from the fractures) occurs in shale gas reservoirs regardless of matrix geometry. They present an equation for predicting the end of this semi-infinite behavior.
Gatens et al.\textsuperscript{36} analyzed production data from about 898 Devonian shale wells in four areas. They present three methods of analyzing production data – type curves, analytical model and empirical equations. The empirical equation correlates cumulative production data at a certain time with cumulative production at other times. This avoids the need to determine reservoir properties. Reasonable matches with actual data were presented. The analytical model is used along with an automatic history matching algorithm and a model selection procedure to determine statistically the best fit with actual data.

Watson et al.\textsuperscript{37} present a procedure that involves selection of the most appropriate production model from a list of models including the dual porosity model using statistics. The analytical slab matrix model presented by Serra et al.\textsuperscript{27} is utilized. Reservoir parameters are estimated through a history matching procedure that involves minimizing an objective function comparing measured and estimated cumulative production. They incorporate the use of a normalized time in the analytical model to account for changing gas properties with pressure. Reasonable history matches were obtained with sample field cases but forecast was slightly underestimated.

Spivey and Semmelbeck\textsuperscript{38} present an iterative method for predicting production from dewatered coal and fractured gas shale reservoirs. The model used is a well producing at constant bottomhole pressure centered in a closed radial reservoir. A slab matrix is incorporated into these solutions. These solutions are extended to the gas case by using an adjusted time and adjusted pressure. Their method also uses a total compressibility term accounting for desorption.
2.4 Horizontal Wells in Naturally Fractured Reservoirs

There have been different traditional approaches to modeling horizontal wells in homogeneous reservoirs. Horizontal wells are normally modeled as infinite conductivity (pressure is uniform along the wellbore). It is not practical, as Gringarten et al.\textsuperscript{39} demonstrated with infinite conductivity fractures, to compute the wellbore pressure from the infinite-conductivity model because of the computational work involved. Gringarten et al.\textsuperscript{39} suggested computing the pressure drop from the uniform flux model (flowrate is the same for each individual segment along a wellbore) at a value of $x_D = 0.732$. This value was the point at which the uniform flux model yields the same results as the infinite conductivity model. This computation has also been incorporated into horizontal well models.\textsuperscript{40-46}

The mathematical problem to be solved for the anisotropic case is usually given by

$$k_x \frac{\partial^2 p}{\partial x^2} + k_y \frac{\partial^2 p}{\partial y^2} + k_z \frac{\partial^2 p}{\partial z^2} = \phi \mu c \frac{\partial p}{\partial t}$$

Several authors have used a model of a line source well in a semi-infinite\textsuperscript{45,47} or infinite reservoir.\textsuperscript{40-44,48-50} Others\textsuperscript{41-44,48,51} have used a line source well in a closed rectangular reservoir. The infinite model has no-flow boundaries at the top and bottom. The semi-infinite reservoir model has three no-flow boundaries (top, bottom and left). The closed reservoir model has all four no-flow boundaries.
It should be noted that in these models, the well is usually not completely penetrating but the models by Ozkan\textsuperscript{41-44} and Odeh and Babu\textsuperscript{51} provide this possibility once the appropriate well and reservoir dimensions are specified.

The differential equation and boundary conditions have been mostly solved by the Newman product method and source functions\textsuperscript{40-45}. These concepts for the homogeneous reservoir case have been extended to model horizontal wells in naturally fractured reservoirs.

Ozkan\textsuperscript{41-44} presents Laplace space solutions for horizontal wells in a reservoir for infinite and closed rectangular boundary cases in terms of $f(s)$. The line source approach previously described is utilized. As demonstrated by Ozkan, there is a possibility of applying this to the naturally fractured reservoir by substituting the appropriate $f(s)$ for a selected matrix geometry.

Carvalho and Rosa\textsuperscript{52} present solutions for an infinite conductivity horizontal well in a semi-infinite reservoir. The reservoir is homogeneous and isotropic. The horizontal well is modeled as a line source. The solutions for the homogeneous case were then extended to the dual porosity case by substituting $s*f(s)$ for $s$ in Laplace space for the pressure derivative (homogeneous). Wellbore storage and skin are incorporated into their model using Laplace space.

Aguilera and Ng\textsuperscript{53} present analytical equations for pressure transient analysis. Their model is a horizontal well in a semi-infinite, anisotropic, naturally fractured reservoir. Transient and pseudosteadystate interporosity flow is considered. Six flow periods are identified –First radial flow (at early times, from fractures), Transition
period, Second radial flow in vertical plane, First linear flow, Pseudoradial flow and Late linear - with expressions for determining skin provided.

Ng and Aguilera\textsuperscript{54} present analytical solutions using a line source and then compute pressure drop on a point away from the well axis to account for the radius of the actual well. A method for determining the numerical Laplace transform is presented. This method was then used to compute the dual porosity response (pseudosteady state). Their solutions were compared to other solutions.

Thompson \textit{et al.}\textsuperscript{55} present an algorithm for computing horizontal well response in a bounded dual porosity reservoir. Their model is a horizontal well in a closed rectangular reservoir. Their procedure involves converting a known analytic solution to Laplace space numerically point by point and then inverting using the Stehfest algorithm.\textsuperscript{56} This is similar to the procedure presented by Ohaeri and Vo\textsuperscript{46} who use a numerical Laplace space algorithm\textsuperscript{57} but also present alternative equations determined by parameter ranges which result in computational efficiency.

Du and Stewart\textsuperscript{58} describe situations which can yield linear flow behavior – a multi-layered reservoir (one layer has a very high permeability relative to the other); naturally fractured reservoir (flow from matrix into horizontal well intersecting fractures); and areal anisotropy (vertical fractures aligned predominantly in one direction). Their model is that of a horizontal well in a homogeneous, infinite acting reservoir. Three flow regimes are identified – radial vertical flow, linear flow opposite completed section and pseudoradial flow at late time. A bilinear flow behavior was also identified.
The model presented in this work has the advantage of being simpler than the horizontal well models. The model will be presented in Chapter III. It also allows the direct use of Laplace space techniques not easily seen with these horizontal well models. Review of literature also shows that the transient linear flow regime has not been investigated in the manner presented in this work.
CHAPTER III
MATHEMATICAL MODEL

3.1 Introduction

A schematic of the model to be used in this work is shown in Fig. 3.1. A rectangular grid is imposed on the microseismic results as shown in Fig. 3.1. The model is shown in detail with representative cube matrix blocks in Fig. 3.2. The features of the model to be used in this work are described below.

- A closed rectangular geometry reservoir containing a network of natural and hydraulic fractures (as in Mayerhofer et al.\textsuperscript{14}). The fractures do not drain beyond the boundaries of this rectangular geometry.
- The perforated length of the well, $x_e$, is the same as the width of the reservoir.
- Flow is towards the well at the centre of the rectangular geometry.
- It is a dual porosity system consisting of matrix blocks and fractures.
- The transient dual porosity solutions presented for a linear model by El-Banbi\textsuperscript{16} are applied and extended to this system. Modifications will be made to this linear model to include the convergence skin accounting for flow towards an actual horizontal well.

The slab matrix model is more commonly used in the literature. This model will be similarly adopted and is shown in Fig. 3.3. The mathematical details of this linear dual porosity model (slab matrix) are given in Appendix B.
Fig. 3.1 – Hydraulically Fractured Horizontal Well in Shale Gas Reservoir. Rectangular grid superimposed on system to represent our model.

Fig. 3.2 – Schematic of Cube Matrix Linear Model of Hydraulically Fractured Well. Cross-sectional area at well face, $A_{cw} = 2x_e h$. 
3.2 Matrix (Slab) Equations

The diffusivity equations for the matrix along with the initial and boundary conditions are given by Eqs. B-4 to B-6 in Appendix B.

\[
\frac{\partial^2 p_{Dlm}}{\partial z_D^2} = \frac{3}{\lambda_{Ac}} (1 - \omega) \frac{\partial p_{Dm}}{\partial t_{Dm}} \tag{3.1}
\]

where \( \lambda_{Ac} = \frac{12 k_m}{L^2 k_f} A_{cw} \) is the Warren and Root interporosity flow parameter.

Initial condition: \( p_{Dlm}(z_D,0) = 0 \)

Inner boundary: \( \left. \frac{\partial p_{Dlm}}{\partial z_D} \right|_{z_D = 0} = 0 \)
Outer boundary: \( p_{DLm} \biggr|_{\tau=1} = p_{DLf} \)

The dimensionless time and pressure variables are given for the slightly compressible fluid by

\[
\frac{t_{DAC}}{(\phi \mu_c^e)_{f+m} \Lambda_{cw}} = \frac{0.00633 k_f t}{(\phi \mu_c^e)_{f+m} \Lambda_{cw}} \text{ and } p_{DLc} = \frac{k_f \sqrt{\Lambda_w (p_i - p_{of})}}{141.2 q \beta \mu}
\]

and for the gas case by

\[
t_{DAC} = \frac{0.00633 k_f t}{(\phi \mu_c^e)_{f+m} \Lambda_{cw}}, \quad m_{DLc} = \frac{k_f \sqrt{\Lambda_w [m(p_i) - m(p_{of})]}}{1422 q_T}
\]

\( k_f \) is defined as the bulk fracture permeability of the dual porosity models.

### 3.3 Fracture Equations

The diffusivity equations for the fracture and the initial and boundary conditions are given by Eq. B-12 in Appendix B. The second term on the right side of the equation represents the source term from the matrix.

\[
\frac{\partial^2 p_{DLf}}{\partial y_D^2} = \frac{\partial p_{DLf}}{\partial x_{DAC}} - \frac{\lambda_h}{3} \left[ \frac{\partial p_{DLc}}{\partial x_D} \right]_{x_D=1}
\]

**Initial condition:** \( p_{DLf} (y_D, 0) = 0 \)

**Inner boundary:** \( \left. \frac{\partial p_{DLf}}{\partial y_D} \right|_{y_D=0} = -2\pi \) (constant rate)

**Outer boundary:** \( \left. \frac{\partial p_{DLf}}{\partial y_D} \right|_{y_D=A_{DAC}} = 0 \) (no-flow boundary)
### 3.4 Constant Pressure Inner Boundary Solution

The solution to the system presented in Eqs. 3.1 and 3.3 in Laplace space is given by Eq. B-23 in Appendix B

\[
\frac{p_{w,DL}}{s\sqrt{f(s)}} = \frac{2\pi}{\sqrt{f(s)}} \left[ \frac{1 + e^{-2\sqrt{f(s)}y_D}}{1 - e^{-2\sqrt{f(s)}y_D}} \right] \quad \text{..................................(3.4)}
\]

Where \( y_D = \sqrt{\frac{y}{k_w}} \)

In Laplace space, the constant \( p_{wf} \) case at the wellbore can be found from the solution for the constant rate case given by Eq. 3.4 using the Van Everdingen and Hurst relation \(^{59}\) given by Eq 3.5

\[
\frac{1}{q_{DL}} = \frac{1}{s^2 p_{w,DL}} \quad \text{..................................(3.5)}
\]

Eq. 3.5 thus becomes for the constant \( p_{wf} \) case

\[
\frac{1}{q_{DL}} = \frac{2\pi}{\sqrt{f(s)}} \left[ \frac{1 + e^{-2\sqrt{f(s)}y_D}}{1 - e^{-2\sqrt{f(s)}y_D}} \right] \quad \text{..................................(3.6)}
\]

Eq. 3.6 can then be inverted to obtain the solutions as a function of time using suitable Laplace numerical inversion algorithms such as Stehfest’s inversion algorithm.\(^{56}\)

### 3.5 Convergence Skin

The convergence skin accounts for distortion of the flow from linear to radial around the wellbore and is given by Lichtenberger \(^{60}\) as

\[
s_c = -\ln \left[ \frac{\pi r_o}{h} \left( 1 + \frac{k_y}{k_H} \right) \sin \left( \frac{\pi l_z}{h} \right) \right] \quad \text{..................................(3.7)}
\]
where \( d_z \) is the distance to the nearest horizontal boundary and \( k_V \) and \( k_H \) are horizontal and vertical permeabilities respectively.

The effect of including the convergence skin into the linear model is illustrated in Fig. 3.4. This accounts for flow towards an actual horizontal well present in the center of the rectangular reservoir distinct from flow towards a plane in the El-Banbi model.\(^{16}\)

\[
\begin{align*}
\text{Fig. 3.4 – Side View of Linear Model (Rectangular Reservoir) with and without Convergence Skin. In the figure on the left, linear flow occurs towards a plane. In the figure on the right, the inclusion of the convergence skin accounts for the distortion of the flowlines from linear to radial around the horizontal wellbore.}
\end{align*}
\]

Equations for the beginning of the stabilization of the convergence skin in linear flow were derived in Appendix I, and are given by Eqs. I-15 and I-20 for the constant rate and constant \( p_{wf} \) cases respectively as

\[
\begin{align*}
t_{p_{MC}} &= \frac{h}{8\pi L_w} \quad \text{constant rate} \\
t_{p_{MC}} &= \frac{h}{2\pi^2 L_w} \quad \text{constant } p_{wf}
\end{align*}
\]
3.6 Validation of Model

In this section, a set of runs will be performed to compare the linear model previously described to *Fekete (WellTest32 Module version 7.0.0.2)*, the numerical simulator *ECLIPSE version 2007.1* and Ozkan’s Laplace space solution\(^{41}\) for horizontal well in a bounded rectangular reservoir. More extensive tests are described in Appendix E.

The problem is to determine the constant rate transient response of a fully penetrating horizontal well in the center of a bounded rectangular reservoir as in Fig. 3.3. The data for the problem set is given in Table 3.1. For simplicity, the reservoir will be assumed to be homogeneous and the fluid slightly compressible.

Ozkan’s Laplace space solution (too lengthy to be reproduced here) is given by Eq. 2.6.42 in his dissertation.\(^{41}\) This is inverted from Laplace space to yield the dimensionless pressure, \(p_{DOzkan}\). An equation for the pseudoskin factor\(^{41,42}\) given below is added to \(p_{DOzkan}\) to yield the horizontal well response.

\[
s = -\frac{1}{2L_D \sqrt{k/k_s}} \ln \left\{ 4 \sin \left( \frac{\pi}{2} (2z_wD + r_wD) \right) \sin \left( \frac{\pi}{2} r_wD \right) \right\}
\]

\[\text{…………………………(3.10)}\]

Ozkan’s dimensionless pressure and time variables are defined as

\[
p_{DOzkan} = \frac{kh (p_t - p_{ef})}{141.2 q B \mu}, \quad t_{DOzkan} = 0.00633 \frac{kt}{\phi \mu c (L_w/2)^2}\]

where \(L_w\) is the length of the horizontal well.

The following is input into Ozkan’s model to adapt it to our test case.

\(x_{eD} = 2, y_{eD} = 1\) (rectangular reservoir dimensions), \(L_D = 33.33, x_{wD} = 1, y_{wD} = 0.5, z_{wD} = 0.5\) (location of well in rectangular reservoir). The response is computed at \(x_D = 0.732, y_D = 0.5, z_D = 0.778\). These dimensionless variables are those defined by Ozkan.\(^{41}\)
where \( x_D = \frac{2x}{L_w \sqrt{k_x}}, y_D = \frac{2y}{L_w \sqrt{k_y}}, z_D = \frac{z}{h}, L_D = \frac{L_w}{2h} \sqrt{\frac{k_z}{k}}, r_{wD} = \frac{r_w}{h} \sqrt{\frac{k_z}{k}}. \)

It is assumed above that \( k_x = k_y = k_z \)

The results from programming Ozkan’s Laplace space solution is checked against the analytical solution given by Eq. 2.6.59 in his dissertation.\(^{41}\) It can be seen from Fig. 3.5 that our results obtained from using Ozkan’s Laplace solution appears to be comparable to the analytical solution.
Fig. 3.5 – Verification of Ozkan’s Laplace Solution for Horizontal Well in a Rectangular Reservoir. The half-slope linear and pseudoradial regions are shown. The Laplace solution appears to be comparable to the analytical solution.

Our linear model (constant rate) solution is given by Eq. 3.4. with \( f(s) = 1 \) for the homogeneous case. The convergence skin is computed as 2.95 from Eq. 3.7.

\[
s_c = -\ln \left( \frac{\pi (0.25)}{30} \left( 1 + \sqrt{\frac{15}{11}} \right) \sin \left( \frac{\pi (15)}{30} \right) \right) = 2.95
\]

This convergence skin is then converted to linear variables using

\[
s_{cAc} = s_c \sqrt{\frac{A_{cw}}{L_w}} = 2.95 \sqrt{\frac{120,000}{2000}} = 0.51
\]

This value is added to the dimensionless pressure using Eq. 3.11

\[
p_{wDL} = p_{DL} + 2\pi s_{cAc} \hspace{1cm} \text{...........................(3.11)}
\]
The $2\pi$ in the definition for skin was given by El-Banbi\cite{16} and will be adopted in the current work.

The dimensionless linear model variables given in Eq. 3.2 is used to convert the results to pressure and time.

The results from the runs are given in Fig. 3.6. It can be observed from Fig 3.6 that the linear model (with convergence skin) matches Fekete and ECLIPSE but differs from Ozkan’s solutions. It is believed that the Ozkan solution differs because of his equation for pseudoskin factor which might not properly account for the convergence skin.

It can thus be concluded that our linear model with the inclusion of the convergence skin is valid for the purposes of this work.

The beginning of the stabilization of the convergence skin can be computed for this example from Eq. 3.8 as

$$t_{pse} = \frac{h}{8\pi w} = \frac{30}{8\pi(2,000)} = 0.000597 \quad \text{..........................(3.12)}$$

The time of intersection of the radial and linear flow periods is determined from the derivative in Fig. 3.6 as 0.00314 days. This time yields a dimensionless time of

$$t_{pse} = \frac{0.00633(1)(0.00314)}{(0.1)(1)(3x10^{-6})(120,000)} = 0.000552 \quad \text{..........................(3.13)}$$

where $A_{cw} = 2(2,000)(30) = 120,000 \text{ ft}^2$

The dimensionless time computed in Eq. 3.13 is similar to that computed from Eq. 3.12. It can thus be concluded that Eq. 3.8 is appropriate.
Fig. 3.6 – Comparison of Linear model (homogeneous, zero skin, closed) with Fekete, ECLIPSE and Ozkan Laplace solution. The convergence skin has been added on to the linear model. The Linear model matches Fekete and ECLIPSE but differs from Ozkan’s solution.
CHAPTER IV

DEVELOPMENT OF ANALYSIS EQUATIONS

4.1 Introduction

The model used to represent the multi-stage hydraulically fractured shale gas well has been described in Chapter III. It should be noted that the slab matrix geometry (shown in Fig. 3.3) is used in this work since it is most commonly used in the literature. Applications to the other matrix geometry types (two-dimensional: cylinder, columns; three-dimensional: sphere, cubes) will be demonstrated in Chapter V. The linear dual porosity model given in El-Banbi\textsuperscript{16} will be used as a basis for the work in this chapter. The mathematical details of this linear dual porosity model are given in Appendix B.

From Eq. 3.6 and B-25, the Laplace space solution for the constant pressure inner boundary, closed outer boundary reservoir (slab matrix) is given by

\[
\frac{1}{q_{DL}} = \frac{2\pi s}{\sqrt{s} f(s) \left[1 + e^{-2\sqrt{s} f(s) y_{ss}}\right]} \left[1 - e^{-2\sqrt{s} f(s) y_{ss}}\right] \quad \text{.........................(4.1)}
\]

where dimensionless variables are defined as

\[
\frac{1}{q_{DL}} = \frac{k_f \sqrt{A_{ww}} \left[m(p_i) - m(p_{uf})\right]}{1422q_T \sqrt{T}} \quad y_{De} = \frac{y_s}{\sqrt{A_{ww}}} \quad \text{.........................(4.2)}
\]

where \( s \) is the Laplace space variable and the inverse is

\[
\tau_{DLc} = \frac{0.00633 k_f t}{(\phi u c_i)_{f+u} A_{cw}}
\]
Additionally for the slab matrix case,

\[ f(s) = \omega + \sqrt{\frac{\lambda_{Ac}}{3s}} (1 - \omega) \tanh \left( \frac{3(1 - \omega)s}{\lambda_{Ac}} \right) \]  

\[ \text{........................................(4.3)} \]

The dual porosity parameters are given by \( \lambda_{Ac} = \frac{12}{L^2} \frac{k_m}{k_f} \lambda_{cw} \) and \( \omega = \frac{(\phi_f)_m}{(\phi_f)_f + (\phi_f)_m} \).

A parametric study conducted with the linear model given by Eq. 4.1 is summarized in Figs. 4.1 and 4.2. Figs. 4.1 and 4.2 show results for reservoir sizes \( y_{De} = 1 \) and 100 for ranges of \( \omega (10^{-3} \text{ and } 10^{-7}) \) and \( \lambda_{Ac} (10^{-3}, 10^{-5} \text{ and } 10^{-7}) \). The homogeneous case (\( \omega = 1 \)) is also added to the plot.

![Fig. 4.1 – Effect of \( \omega \) and \( \lambda_{Ac} \) on Linear Model Response (\( y_{De} = 1 \)). \( \lambda_{Ac} = 10^{-3}, 10^{-5}, 10^{-7} \) for values of \( \omega = 10^{-3} \) and \( 10^{-7} \). There is no effect of \( \omega \) on the late time transient linear response for a fixed \( \lambda_{Ac} \).]
It can be observed from Fig. 4.1 that the homogeneous response is above the dual porosity response. It can also be observed that for $\omega = 10^{-3}$, all the responses for $\lambda_Ac = 10^{-3}, 10^{-5}, 10^{-7}$ converge to the same initial half-slope (indicative of linear flow in the fractures) at early times and different half slopes at later times. The half slope at later times is indicative of linear flow in the matrix. As $\omega$ decreases to $10^{-7}$ (dotted lines), the common initial half slope disappears and the responses show only the late time half slopes. The late time responses for each of the $\lambda_Ac$ is similar for $\omega = 10^{-3}$ and $10^{-7}$. It can thus be concluded that there is no effect of $\omega$ on the late time transient response for a particular $\lambda_Ac$. It can also be concluded that the initial half slope region preceding the later time half slope region is only evident as $\lambda_Ac$ and $\omega$ increases.

![Graph showing the effect of $\omega$ and $\lambda_Ac$ on Linear Model Response (yDe = 100). $\lambda_Ac$ = $10^{-3}, 10^{-5}, 10^{-7}$ for values of $\omega = 10^{-3}$ and $10^{-7}$ The parameters $\omega$ and $\lambda_Ac$ affect the transient response significantly.](image-url)
The parameters in Fig. 4.2 are similar to Fig. 4.1 except that $y_{De}$ has increased from 1 to 100. Similar to Fig. 4.1, the homogeneous response is above the dual porosity response. It can be observed from Fig. 4.2 that the $\omega=10^{-3}$ cases also indicate the common initial half-slope and then progressively indicate a quarter slope (bilinear flow caused by simultaneous linear flow in the matrix and fractures). The $\lambda_{Ac}=10^5$, $\omega=10^{-3}$ and $\lambda_{Ac}=10^7$, $\omega=10^{-3}$ cases indicate a bilinear flow followed by linear flow (half-slope). As $\omega$ decreases to $10^{-7}$ (dotted lines), the early linear flow disappears and the only transient responses are bilinear ($\lambda_{Ac}=10^3$, $\omega=10^{-7}$) and bilinear followed by linear ($\lambda_{Ac}=10^5$, $\omega=10^{-7}$ and $\lambda_{Ac}=10^7$, $\omega=10^{-7}$).

It appears that relatively large $\lambda_{Ac}$ and $\omega$ result only in the bilinear transient flow. As $\lambda_{Ac}$ and $\omega$ decrease, bilinear followed by an increasing transient linear regime is observed.

It can be concluded from Figs. 4.1 and 4.2 that relatively smaller $y_{De}$ reservoirs exhibit long periods of late-time transient linear flow only as shown in Fig. 4.1 and bilinear flow occurs with large reservoirs.

There are thus five flow regions identified and equations are subsequently presented for each region. All the equations are derived beginning with Eq. 4.1. The details of the development are shown in Appendix C. The flow regimes are illustrated in Fig. 4.3.
4.2 Region 1

This represents early transient linear flow in the fracture system only. There is negligible drainage from the matrix. This occurs at early times as shown in Fig 4.3. As shown in Eq. C-11 in Appendix C-1, the equation is given by

\[ q_{DL} = \frac{1}{2\pi \sqrt{m_{DAc} / \omega}} \]  

……………………………(4.4)

and the approximate valid range is given by Eq. C-17

\[ 0 < t_{DAc} < \frac{y_{De} \omega}{9} \]  

……………………………(4.5)
Applying the dimensionless pressure and time definitions given in Eq. 4.2 to convert Eq. 4.4 to usual variables yields

\[ \sqrt{k_f A_w} = \frac{1262T}{\sqrt{\alpha(\phi_r)} f_{st}} \frac{1}{\bar{m}_1} \] ..............................(4.6)

Where \( \bar{m}_1 \) is the slope obtained from a plot of \( \frac{m(p_i) - m(p_{of})}{q_g} \) against \( \sqrt{t} \).

If Region 1 is observed, Eq. 4.6 may be used to determine the fracture permeability if the other parameters are known.

### 4.3 Region 2

This represents bilinear flow caused by simultaneous transient flow in the fracture system and matrix. It is indicated by a one-quarter slope on a log-log plot as shown in Fig. 4.3. As shown in Eq. C-27 in Appendix C-2, the equation is given by

\[ q_{dl} = \frac{2^{0.25}}{10.133^{0.25}} A_{Ac} \] ..............................(4.7)

This region has been found occur only when \( y_{De} > \sqrt{3/\lambda_{Ac}} \). Otherwise it bends down to Region 4 as shown in Fig. 4.3. This region is valid approximately when \( t_{DaAc} < \frac{1}{3\lambda_{Ac}} \) or

\[ t_{DaAc} < \left( \frac{y_{De}}{3} \right)^{4} \frac{\lambda_{Ac}}{3} \] ..............................(4.8)

as shown in the derivations given in Appendix C (Eq. C-36)

Applying the dimensionless pressure and time definitions given in Eq. 4.2 to convert Eq. 4.7 to usual variables yields
\[ \sqrt{k_f A_{cw}} = \frac{4064 T}{\left[ \sigma_m (\phi \mu c_i) f_m \right]^{0.25} \tilde{m}_2} \]  

(4.9)

Where \( \tilde{m}_2 \) is the slope obtained from a plot of \( \frac{m(p_i) - m(p_{nf})}{q_g} \) against \( t^{0.25} \).

If Region 2 is observed, Eq. 4.9 may be used to determine the fracture permeability and the shape factor, \( \sigma \), if the other parameters are known.

### 4.4 Region 3

This represents the homogeneous reservoir case response (An equation for the complete analytical homogeneous reservoir transient response is given in Appendix D). This is also indicated by a one-half slope on a log-log plot as shown in Fig. 4.3. As shown in Appendix C-3, the equation is given by Eq. C-44

\[ q_{DLh} = \frac{1}{2\pi \sqrt{A_{ch}}} \]  

(4.10)

Where \( \frac{1}{q_{DLh}} = k \left[ A_{cw} \frac{m(p_i) - m(p_{nf})}{1422 q_g T} \right] \); \( t_{DLh} = \frac{0.00633 k t}{\phi \mu c_i} A_{cw} \) and \( k \) is the homogeneous reservoir permeability.

This region has been found occur only when \( y_{De} \geq \sqrt{3\phi \mu c_i / \lambda_{Ac}} \).

This region is valid approximately when \( t_{DLh} < \frac{y_{De}^2}{9} \)  

\[ \]  

(4.11)

as shown in the derivations given in Appendix C (Eq. C-50).

Applying the dimensionless pressure and time definitions given in Eq. 4.2 to convert Eq. 4.10 to usual variables yields...
\[ \sqrt{k} A_{cw} = \frac{1262T}{\sqrt{\phi m^*}} \frac{1}{\bar{m}_3} \] ...................................................(4.12)

where \( \bar{m}_3 \) is the slope obtained from a plot of \( \frac{m(p_i) - m(p_{of})}{q_e} \) against \( \sqrt{t} \).

If Region 3 is observed, Eq. 4.12 may be used to determine the bulk reservoir permeability if the other parameters are known.

### 4.5 Region 4

This represents the transient linear case when the transient response is primarily from drainage of the matrix from the outer edges towards the matrix block centers. This is also indicated by a one-half slope on a log-log plot as shown in Fig. 4.3. As shown in Appendix C-4, the equation is given by Eq. C-61

\[ q_{DL} = \frac{1}{2\pi \sqrt{\pi D_{Ac}}} \sqrt{\frac{3}{3} y_{De}} \] ...................................................(4.13)

and the approximate valid range is given by Eq. C-73

\[ \frac{\lambda_{Ac}}{3} \left( \frac{y_{De}}{0.5} \right)^4 \frac{1}{t_{DAc}} < \frac{1}{3\lambda_{Ac}} \] ...................................................(4.14)

Applying the dimensionless pressure and time definitions given in Eq. 4.2 to convert Eq. 4.13 to usual variables along with Eqs. 4.15 and 4.16 (for the slab matrix case) yields Eq. 4.17

\[ \lambda_{Acw} = \frac{12}{L^2} \frac{k_m}{k_f} A_{cww} \] ...................................................(4.15)

\[ A_{cw} = \frac{L}{2y_e} A_{cm} \] ...................................................(4.16)
\[ \sqrt{k_m A_{cm}} = \frac{1262T}{\sqrt{(\phi \mu c_m)_m}} \frac{1}{\bar{m}_4} \] ...........................................(4.17)

where \( \bar{m}_4 \) is the slope obtained from a plot of \( \frac{[m(p_l) - m(p_w)]}{q_s} \) against \( \sqrt{t} \). It is also assumed that \( (\phi \mu c_i)_f = (\phi \mu c_i)_m \). If Region 4 is observed, Eq. 4.17 may be used to determine the matrix drainage area, \( A_{cm} \), if the other parameters are known.

It should be noted that Eq. 4.13 can be written as

\[ q_{Dlm} = \frac{1}{2 \pi} \sqrt{\pi_{Dlm}} \] ...........................................(4.18)

where

\[ \frac{1}{q_{Dlm}} = \frac{k_m \sqrt{A_{cm}[m(p_l) - m(p_w)]}}{1422q_sT} \]

\[ t_{Dlm} = \frac{0.00633k_m t}{(\phi \mu c_i)_m A_{cm}} \]

and \( k_m \) is the reservoir matrix permeability.

Eq. 4.18 can easily be converted to Eq. 4.17.

This implies that Region 4 depends only on matrix properties \( k_m \) and \( A_{cm} \) and is not affected by fracture flow properties.

### 4.6 Region 5

This represents the period when the reservoir boundary begins to influence the transient response as shown in Fig. 4.3. The transient response in the matrix blocks have reached their central inner no-flow symmetry lines. No equation is presented for this region in this study. Unlike the slightly compressible fluid case (liquid), the use of pseudopressure relations for gas to linearize and solve the diffusivity equation will only be accurate for the transient regions (Regions 1 to 4). The boundary dominated Region 5 requires the use of the following equations simultaneously.
\[ q_g = J_{CP} \left[ m(p) - m(p_{wf}) \right] \]  ...........................................(4.18)

where \( J_{CP} \) is the productivity index for the constant pressure case.

and

\[ \frac{\bar{p}}{\bar{z}} = \left( \frac{\bar{p}}{\bar{z}} \right)_i \left[ 1 - \frac{G_p}{G} \right] \]  ...........................................(4.19)

Which is the material balance equation for a closed gas reservoir.

All the derived equations are summarized in Tables 4.1. A summary of the equivalent equations for the constant rate inner boundary case is also presented in Table 4.2.

The effect of $y_{De}$ on Region 4 response is shown in Figs. 4.4 to 4.7. The slab matrix dual porosity linear reservoir transient response is compared with the equations for Region 3

\[ q_{dl} = \frac{1}{2\pi \sqrt{\frac{D_{Ac}}{D_{De}}}} \] and Region 4 \( q_{dl} = \frac{1}{2\pi \sqrt{\frac{D_{Ac}}{D_{De}}} \sqrt{\frac{A_{Ac}}{3} y_{De}}} \) in Figs. 4.4 and 4.5 to show the effect of small ($y_{De} = 1$) and relatively larger ($y_{De} = 10^5$) reservoirs. It can be observed that for the small reservoir in Fig. 4.4, the slab matrix response matches the equation for Region 4. For the larger reservoir in Fig. 4.5, the slab matrix response indicates a bilinear region at early times and matches the equation for Region 3 at later times.

The slab matrix dual porosity transient response is shown in Figs. 4.6 and 4.7 for several values of $y_{De}$. It can be observed from Fig. 4.6 and 4.7 that the transient response for Region 4 curves downwards when $y_{De} < \sqrt{5 D_{Ac} / \lambda_{Ac}}$ and is not evident when $y_{De} \geq \sqrt{3 D_{Ac} / \lambda_{Ac}}$.

### 4.7 Summary

Five flow regions have been identified with the linear dual porosity model and derived equations were presented for four of the regions. Analysis equations were also presented for the region along with the criteria for existence of each of these regions. It has been shown that the dimensionless reservoir size, $y_{De}$ has an important effect on Region 4 transient response.
Fig. 4.4 – Effect of Small Reservoir Size on Region 4 ($y_D = 1$, $\lambda_{Ac} = 10^{-4}$, $\omega = 10^{-5}$). The half slope region on the slab matrix (dual porosity, constant $p_{wf}$, closed) response matches the equation shown previously for Region 4.

Fig. 4.5 – Effect of Large Reservoir Size on Region 4 ($y_D = 10^5$, $\lambda_{Ac} = 10^{-4}$, $\omega = 10^{-5}$). The half slope region on the slab matrix (dual porosity, constant $p_{wf}$, closed) response matches the equation shown previously for Region 3 (homogeneous) and not that for Region 4 as shown in Fig. 4.4.
Fig. 4.6 – Effect of $y_{De}$ (Case A - slab matrix dual porosity, constant $p_{wf}$, closed). The usual half slope (Region 4) initially curves down only when $y_{De} < \sqrt{3\omega/\lambda_{Ac}}$.

Fig. 4.7 – Effect of $y_{De}$ (Case B - slab matrix dual porosity, constant $p_{wf}$, closed). There is no evident half slope (Region 4) when $y_{De} \geq \sqrt{3/\lambda_{Ac}}$ but a bilinear region (Region 2).
CHAPTER V

TRANSIENT LINEAR FLOW REGIME (REGION 4)

5.1 Introduction

The transient linear regime is the regime in which the response is dominated by matrix drainage and was described as Region 4 in Chapter IV. Matrix block drainage of different geometries have been shown in detail to exhibit the transient linear drainage in Appendix A. This chapter deals with Region 4 in detail and summarizes the effects of shape factors and area-volume ratios. A preliminary procedure is presented for analyzing field data with zero skin and is illustrated with a synthetic case.

5.2 Effect of Shape Factors

The term shape factor as used in this work refers to the parameter first presented by Warren and Root\textsuperscript{18} to describe matrix geometry and utilized in their pseudosteady-state matrix-transfer equation. Several authors\textsuperscript{61-69} have investigated and shown their values for these shape factors. The Warren and Root shape factors have been factored into the commonly used transient dual porosity models (illustrated in Appendix B). It will be shown that other shape factors can be factored into the transient dual porosity models with consistent appropriate modifications. In this work, the shape factors given by Warren and Root, Kazemi and Zimmerman will be used for comparison.
As previously mentioned, the Warren and Root shape factor formulation for the slab matrix geometry \((12/L^2)\) is inherent in \(f(s)\) as shown in Appendix B. The Kazemi and Zimmerman relations for the shape factor can be similarly substituted into the transient dual porosity model as was shown in Appendix B. This is summarized in Table 5.1.

<table>

</tr>
</tbody>
</table>

The generalized test run procedure is illustrated for the slab matrix, rectangular geometry reservoir case with the Warren and Root shape factor case. It was previously illustrated for the radial geometry case. The dataset is given in Table 5.2.

a) Select a shape factor formulation (e.g. Warren and Root)

b) Compute a value for the shape factor (e.g. slab matrix) \(\sigma = \frac{12}{(50)^2} = 4.8 \times 10^{-3}\)

c) Compute \(\lambda_{A_c} = \sigma \frac{k_{m}}{k_{f}} A_{cw} = (4.8 \times 10^{-3}) \left(\frac{10^{-5}}{100}\right) (8 \times 10^5) = 3.84 \times 10^{-4}\)
d) Ensure appropriate $f(s)$ from Table 5.1 (in this case, Warren and Root) is programmed in transient dual porosity model.

e) Run program with computed $\lambda_{Ac}$ and given $\omega$

The results from the runs are compared in Fig. 5.1. It can be observed from Fig. 5.1 that the different shape factor formulations – Warren and Root, Kazemi and Zimmerman - result in the same transient linear response. It can thus be concluded that any shape factor formulation can be utilized as long as the appropriate $f(s)$ formulation is used along with the consistent $\lambda_{Ac}$ equation and calculations. More importantly, programs that have the Warren and Root formulation correctly programmed can be utilized. This conclusion has also been verified for the cylinder and sphere geometries.
Fig. 5.1 - Effect of Shape Factors on Transient Linear Response (slab matrix case; $\omega=10^{-3}$; W&R : $\lambda_{Ac}=3.84\times10^{-4}$; Kazemi : $\lambda_{Ac}=1.28\times10^{-4}$; Zimmerman : $\lambda_{Ac}=3.16\times10^{-4}$). The shape factors result in the same transient linear response once the corresponding $f(s)$ changes are made consistent with the $\lambda_{Ac}$ definition.

5.3 Effect of Area-Volume Ratio

In this section, the transient dual porosity response of different matrix geometry (slab, cylinder and sphere) will be compared. Two cases are presented.

Case 1 is one in which the different matrix geometry transient dual porosity models are run with the same $\lambda_{Ac}$ ($3.84\times10^{-4}$). The dataset is the same as in Table 5.2. The Warren and Root shape factors were used for the three matrix geometries. Slab: $12/L^2$, Cylinder: $32/D^2$, Sphere : $60/D^2$. The results are presented in Figs. 5.2 and 5.3. It can be observed that the transient linear responses are different for all the geometries.
Case 2 is one in which the area-volume ratios for all the three matrix geometry
are made equivalent. The dataset is given in Table 5.3. The area-volume ratios are given
thus:

Slab (One-dimensional) \( \frac{2}{L_1} \)

Cylinder/Column (Two-dimensional) \( \frac{4}{D} \text{ or } \frac{4}{L_2} \)

Sphere/Cube (Three-dimensional) \( \frac{6}{D} \text{ or } \frac{6}{L_3} \)

It is noticed that the area-volume ratios for the two-dimensional case, \( \frac{4}{D} \) and \( \frac{4}{L_2} \) will
be the same if the fracture spacings \( D \) and \( L_2 \) are equivalent. This observation also
applies to the three-dimensional cases if \( D \) and \( L_3 \) are equivalent. This allows the use of
transient dual porosity models with the cylinder and sphere as good approximations for
the two-dimensional and three-dimensional cases (since the transient dual porosity
models are actually developed and programmed with simpler cylinder and sphere
geometries instead of the more realistic column and cube geometries).

Dimensions for the slab, cylinder and sphere were selected as 50, 100 and 150 ft
respectively to ensure similar area/volume ratios of 0.04. The parameter, \( \lambda_{Ac} \) is computed
for each geometry and then run in the transient dual porosity model. The results are
presented in Figs. 5.4 and 5.5. It can be observed that the initial transient linear
responses are similar for all the geometries before the effect of the boundary.

Fig. 5.2 - Log-log Plot of $q_{DL}$ against $t_{DAC}$ - Effect of Matrix Geometry on Transient Response Case 1. Similar $\lambda_{Ac}$ ($\omega=10^{-3}$; $\lambda_{Ac}=3.84 \times 10^{-4}$). The three geometries result in different transient linear responses.
Fig. 5.3 – Specialized Plot of $1/q_{DL}$ against $t_{DAc}^{0.5}$ - Effect of Matrix Geometry on Transient Response Case 1. Similar $\lambda_{Ac}$ ($\omega=10^{-3}$; $\hat{\lambda}_{Ac}=3.84 \times 10^{-4}$). The three geometries result in different transient linear responses.

Fig. 5.4 – Log-log Plot of $q_{DL}$ against $t_{DAc}$ - Effect of Matrix Geometry on Transient Response Case 2. Area-volume ratio is 0.04 for all geometries. (slab: $\lambda_{Ac} = 3.84 \times 10^{-4}$; $L=50$ ft; cylinder: $\lambda_{Ac} = 2.56 \times 10^{-4}$, $D=100$ ft; sphere: $\lambda_{Ac} = 2.13 \times 10^{-4}$, $D=150$ ft). The three geometries result in similar initial transient linear responses.
The results from these cases illustrate the importance of the area-volume ratio in obtaining similar transient linear response from any matrix geometry. This significant result ensures that we can develop a method for analysis of the transient linear regime for geometry that incorporates the area-volume ratio.

It can be concluded that the matrix drainage area, $A_{cm}$ has to be the same for all matrix geometries in order to achieve the same transient linear response.

It can also be concluded that for the same reservoir, the fracture spacings for the one, two and three-dimensional matrix geometries have to be in the ratio of 1:2:3 in order to achieve the same transient linear response. These results and conclusions have also been verified using the other shape factor formulations- Zimmerman and Kazemi.
5.4 Data Analysis Procedure

Results from the previously described sections are combined to develop a preliminary practical method of analyzing field data. The following procedure for determining the fracture spacing is presented.

a) Obtain field production rate data.

b) Check for half slope on log-log plot of rate against time indicating the transient linear flow regime. Also check for a straight line on a plot of \( \frac{(m(p,i)-m(p,w))}{q_i} \) against \( \sqrt{t} \).

c) Determine \( \sqrt{k_m A_m} \) from

\[
\sqrt{k_m A_m} = \frac{1262T}{\sqrt{(\phi k_c)}_{r+m}} \frac{1}{\bar{m}_i} \quad \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdOTS FOR THE PAGE
5.5 Application of Procedure to Synthetic Case

In this section, the field analysis procedure is demonstrated with synthetic data generated using the transient dual porosity model (rectangular geometry, slab matrix blocks) analytical solutions. Data used for this illustration is given in Table 5.4. Calculated parameters are also shown in Table 5.4.

5.5.1 Problem Formulation

Since we know the data in Table 5.4, we can calculate certain values for our synthetic case.

The cross-sectional area is computed from

\[ A_w = 2x h = 2(2,000)(200) = 8 \times 10^5 \text{ ft}^2 \]

The matrix drainage area is computed from

\[ A_m = \frac{2}{V_b} \text{ (area-volume relation for the slab)} \]

and with \( V_b = A_e y_e \); \( A_m = \frac{2y_e A_w}{L} = \frac{2(500)}{50} (8 \times 10^5) = 1.6 \times 10^7 \text{ ft}^2 \)

The interporosity flow parameter is computed as

\[ \lambda_{Ac} = \frac{12}{L^2} \frac{k_m}{k_f} A_w = \frac{12}{(50)^2} \left( \frac{10^{-5}}{100} \right) (8 \times 10^5) = 3.84 \times 10^{-4} \]

The transient dual porosity model is then run with \( \lambda_{Ac} = 3.84 \times 10^{-4}, \omega = 10^{-3} \) and \( y_{De} = y_e / \sqrt{A_c w} = 0.559 \). The following equations for dimensionless pressure and time are then used to convert to rate and time values used to plot Fig. 5.6.

\[ \frac{1}{q_{DL}} = \frac{k_f}{1422q_g T} \sqrt{A_c w} \left[ m(p_i) - m(p_wf) \right] ; \quad t_{DAC} = \frac{0.00633k_f t}{(\phi k_i) f_m A_c w} \]

Fig. 5.6 – Log-log Plot of Rate against Time - Synthetic Case. Data was generated using the transient dual porosity model (rectangular geometry, linear flow, slab matrix).

5.5.2 Application

The data indicates a half-slope as shown in Fig. 5.6. The next step is to make a plot of 
\[
\frac{m(p_i)-m(p_{wf})}{q_g} \text{ against } \sqrt{t}
\]
as shown in Fig. 5.7 using the synthetic data generated in Fig. 5.6. As previously stated, it will be assumed that \((\phi_u c_v)_{f+m}\) (the total system - matrix and fractures) is approximately the same as \((\phi_u c_v)_{m}\) for the matrix only. The parameter \((\phi_u c_v)_{m}\) is also computed using properties at initial reservoir pressure of the gas equations.
The slope, \( \tilde{m}_4 \) is determined from Fig. 5.7 as 16,250 psi/cm²/ft/day.

And, \( \sqrt{k_mA_m} = \frac{1262T}{\sqrt{(\phi \mu_c)_{f+m}}} \tilde{m}_4 = \frac{1262(660)}{\sqrt{(0.15)(0.0224)(304.02 \times 10^{-6})(16,250)}} = 5.07 \times 10^4 \text{ md}^{0.5} \text{ ft}^2 \)

If we can estimate the matrix permeability \( k_m = 10^{-5} \) md for this synthetic case) then we can calculate

\[
A_m = \frac{5.07 \times 10^4}{\sqrt{10^{-5}}} = 1.6 \times 10^7 \text{ ft}^2
\]

This computed \( A_m \) value is the same as the expected value given in Section 5.5.1.

Assuming one-dimensional (slab) matrix geometry;

The fracture spacing is determined from Eq. 5.2 as \( L_1 = \frac{2y_e}{A_{cm} A_w} = \frac{2(500)}{1.6 \times 10^7} (8 \times 10^5) = 50 \text{ ft} \)

This fracture spacing value is similar to the expected value given in Section 5.5.1.

The calculations for our synthetic case were done for our slab matrix block case since this was used to generate the data. If we did not know that this was a slab matrix geometry case and assumed that it was a two-dimensional (column) case, then we can calculate the fracture spacing from Eq. 5.3 as \( L_2 = \frac{4y_e}{A_{cm} A_w} = \frac{4(500)}{1.6 \times 10^7} (8 \times 10^5) = 100 \text{ ft} \)

If we assume that it was a three-dimensional (cube) matrix geometry, then we can similarly calculate the fracture spacing from Eq. 5.4 as

\[
L_3 = \frac{6y_e}{A_{cm} A_w} = \frac{6(500)}{(1.6 \times 10^7)} (8 \times 10^5) = 150 \text{ ft}
\]
Fig. 5.7 – Specialized Plot of \( \frac{[m(p_i) - m(p_{wf})]}{q_k} \) against \( t^{0.5} \) - Synthetic Case. Data was generated using the transient dual porosity model (rectangular geometry, linear flow, slab matrix).

It has been shown that the matrix drainage area, \( A_{cm} \) and (effective) fracture spacings \( (L_1, L_2, \text{ and } L_3) \) can be calculated using our procedure, if \( k_m \) can be estimated. However, there is no way to determine whether the slab, column, or cube case actually applies to a particular well. But it has been shown that the values of \( (L_1, L_2, \text{ and } L_3) \) are in the ratios 1:2:3. In addition to production rate, these calculated values may be useful in determining the effectiveness of the hydraulic fracture treatments. Smaller fracture spacings result in higher gas rates and recovery factors as shown by Mayerhofer et al.\(^{14}\). These calculated values may be used to compare the effectiveness of the fractured systems of different wells. It should be remembered that \( (\phi \mu c_i) \) should be calculated at initial pressure for all equations, as is always done for the gas equations.
It should be noted that the skin effect has been assumed to be zero in all that has been presented in this chapter. The effect of skin will be discussed in detail in Chapter VI.

5.6 Summary

The transient linear flow regime (Region 4) was studied in detail. Different shape factor formulations were shown to result in similar Region 4 response when appropriate $f(s)$ modifications consistent with $\lambda_{Ac}$ computations are made. A preliminary procedure for analyzing field data was presented. This was illustrated with a synthetic case. The parameter $A_{cm}$ can be obtained with available limited data.
CHAPTER VI
CONSTANT BOTTOMHOLE PRESSURE EFFECT OF SKIN IN LINEAR GEOMETRY

6.1 Introduction

Skin is normally defined as a dimensionless pressure for the slightly compressible fluid case given for the radial case by

\[ s_{rw} = \frac{k h \Delta p_s}{141.2 q B \mu} \] ..............................(6.1)

Where the skin is an additional dimensionless pressure

\[ p_{wd} = p_D + s_{rw} \] ..............................(6.2)

\( s_{rw} \) is the skin for the radial case and \( p_D \) is the solution without skin

The Laplace space solution solution for an infinite homogeneous radial reservoir with skin and zero wellbore storage (constant rate inner boundary) is given by

\[ p_{D_{rw}} = \frac{K_s \sqrt{s} + s_{rw} \sqrt{s} K_1 \sqrt{s}}{s \sqrt{s} K_1 \sqrt{s}} \] ..............................(6.3)

The corresponding Laplace space solution for the constant \( p_{wf} \) inner boundary can be obtained by the Van Everdingen and Hurst\(^{59}\) relation given by

\[ p_{D_{rw}} = \frac{1}{s^2 q_{D_{rw}}} \] ..............................(6.4)
The solution is thus obtained from Eq. 6.4 as

\[ \frac{1}{q_{Drw}} = \frac{sK_a(\sqrt{s}) + s_{rw} \sqrt{s}K_1(\sqrt{s})}{\sqrt{s}K_1(\sqrt{s})} \]  

……………………………….. (6.5)

The constant rate solution from Eq. 6.3 is inverted from Laplace space and plotted for \( s_{rw} = 0 \) and \( s_{rw} = 10 \) on a semilog plot in Fig. 6.1. It can be observed from Fig. 6.1 that the two responses are parallel and there is a constant offset of 10 from the \( s_{rw} = 0 \) case.

The constant \( p_{wvf} \) solution from Eq. 6.5 is inverted from Laplace space and plotted for \( s_{rw} = 0 \) and \( s_{rw} = 10 \) on a semilog plot in Fig. 6.2. It can be observed from Fig. 6.1 that the two responses are parallel and there is a constant offset of 10 from the \( s_{rw} = 0 \) case.

Both the constant rate and constant \( p_{wvf} \) cases are plotted in Fig. 6.3. It can be observed that the responses are similar for constant rate and constant \( p_{wvf} \). It can thus be concluded that the effect of skin on constant rate and constant \( p_{wvf} \) for the radial reservoir are similar. The constant rate \( p_{wvf} \) effect has also been confirmed with simulation as shown in Appendix E.

### 6.2 Effect of Skin in Linear Reservoir

The Laplace space solution for an infinite homogeneous linear reservoir with skin and zero wellbore storage (constant rate inner boundary) is given by

\[ p_{WDLb} = \frac{2\pi}{s^{\sqrt{s}}} \left[ 1 + s_{Ach} \sqrt{s} \right] \]  

……………………………….. (6.6)

where \( s_{Ach} \) is the skin and \( s \) is the Laplace space variable.

Eq. 6.6 will also govern the response of the closed linear reservoir at early times.
Fig. 6.1 – Effect of Skin on Radial Reservoir Model (Constant rate, homogeneous, infinite) for $s_{rw} = 0$ and 10. Semilog plot. The two responses are parallel and there is a constant offset of 10 from the $s_{rw} = 0$ case.

Fig. 6.2 – Effect of Skin on Radial Reservoir Model (Constant $p_{wf}$, homogeneous, infinite) for $s_{rw} = 0$ and 10. Semilog plot. The two responses are parallel and there is a constant offset of 10 from the $s_{rw} = 0$ case.
Fig. 6.3 – Effect of Skin on Radial Reservoir Model (Comparing constant rate and $p_{w,f}$, homogeneous, infinite) for $s_{rw} = 0$ and 10. Semilog plot. It can be observed that the responses are similar for constant rate and pressure.

It can be observed from Eq. 6.6 that

$$\frac{1}{p_{WDLh}} = \frac{2\pi}{s\sqrt{s}} + \frac{2\pi A_{ch}}{s} \quad \cdots \quad \text{.........................(6.7)}$$

Inverting from Laplace space

$$p_{WDLh} = 2\pi 2 \sqrt{\frac{t_{DAch}}{\pi}} + 2\pi A_{ch} = 4\sqrt{\frac{\pi}{A_{ch}}} + 2\pi A_{ch} \quad \text{..........................(6.8)}$$

Where $p_{WDLh} = k \sqrt{A_{w}} \left[m(p_r) - m(p_{wf}) \right] / 1422q_T$; $t_{DAch} = \frac{0.00633kT}{(\phi + 6)}$ and $k$ is the homogeneous reservoir permeability.
From Eq. 6.8, the first term on the right hand side is the curve through the origin and the second term is the skin term. This is illustrated in Fig. 6.4 where the \( s_{Ach} = 10 \) case is parallel to the \( s_{Ach} = 0 \) case with a constant offset of \( 2\pi s_{Ach} \). The skin effect was defined as \( 2\pi s_{Ach} \) for the linear model by El-Banbi.\textsuperscript{16}

---

**Fig. 6.4** – Effect of Skin on Linear Reservoir Model (Constant rate, homogeneous, infinite) for \( s_{Ach} = 0 \) and 10. The two responses are parallel and there is a constant offset of \( 2\pi(10) \) from the \( s_{Ach} = 0 \) case.
Fig. 6.5 – Effect of Skin on Linear Reservoir Model (Constant $p_{wf}$, homogeneous, infinite) for $s_{Ach} = 0$ and 10. The $s_{Ach} = 10$ case is not parallel to the $s_{Ach} = 0$ case. The difference between the two curves diminish with time.

Fig. 6.6 – Effect of Skin on Linear Reservoir Model (Constant $p_{wf}$, homogeneous, infinite) for $s_{Ach} = 0$ and 10. The constant rate case is different from the constant pressure case. Note that the constant rate case with $s_{rw} = 0$ and 10 are parallel whereas the constant $p_{wf}$ case with $s_{rw} = 10$ converges to $s_{rw} = 0$ case at later times.
The Laplace space solution for an infinite homogeneous linear reservoir with skin and zero wellbore storage for the constant pressure inner boundary using Eq. 6.6 is given by

\[
\frac{1}{q_{DLh}} = \frac{2\pi s}{\sqrt{s}} \left[ 1 + s_{Ach} \sqrt{s} \right]
\]

where \( s_{Ach} \) is the skin (homogeneous case) and \( s \) is the Laplace space variable.

Details of the derivation of the skin effect for the constant pressure case are provided in Appendix F.

From Eq. 6.9

\[ q_{DLh} = \frac{1}{2\pi \sqrt{s} \left[ 1 + s_{Ach} \sqrt{s} \right]} \]

Solving by partial fractions, Eq. 6.10 can be expressed as

\[
q_{DLh} = \frac{1}{2\pi \sqrt{s}} + \frac{s_{Ach}/2\pi}{1 + s_{Ach} \sqrt{s}}
\]

Inverting from Laplace space, from Eq. F-10,

\[
q_{DLh} = \frac{1}{2\pi s_{Ach}} e^{\left( \frac{t_{max}}{s_{Ach}} \right)} \text{erfc}\left( \sqrt{t_{Dach}} s_{Ach} \right)
\]

Eq. 6.12 gives the transient response for an infinite homogeneous, constant pressure inner boundary reservoir with a skin effect, \( s_{Ach} \) present. This is not the same as the constant rate case as illustrated in Figs. 6.5 and 6.6. For the constant pressure case, the skin effect diminishes with time. These results from the linear reservoir case are different from previous observations for the radial case. Eq. 6.12 is confirmed by comparing with the Laplace space inversion of Eq. 6.9 in Fig. 6.7.
It can be observed from Eq. 6.12 that at small times as \( t_{Dach} \approx 0 \)

\[
q_{DLh} = \frac{1}{2\pi \sqrt{D_{ach}}} 
\]

............................(6.13)

It can also be observed from Eq. 6.12 that at large times as \( t_{Dach} \approx \infty \).

Using the first term in the asymptotic expansion for \( \text{erfc}(x) \) for large \( x \)

\[
\text{erfc}(x) = \frac{e^{-x^2}}{x \sqrt{\pi}} 
\]

............................(6.14)

Eq. 6.12 becomes

\[
q_{DLh} = \frac{1}{2\pi \sqrt{D_{ach}}} 
\]

............................(6.15)

These results explain observations in Fig. 6.6 where the constant pressure response for \( s_{Ach} = 10 \) ranges from the reciprocal of \( \frac{1}{2\pi \sqrt{s_{Ach}}} \) at approximately zero time until it approaches the reciprocal of \( \frac{1}{2\pi \sqrt{D_{ach}}} \) at late times.

The following empirical equation has also been found to fit the constant \( p_{wf} \) response shown in Fig. 6.5

\[
\frac{1}{q_{DLh}} = 2\pi \sqrt{D_{ach}} + \frac{2\pi s_{Ach}}{0.8\sqrt{D_{ach}}} 
\]

............................(6.16)

An expression for the square root of time derivative given by \( \frac{d}{dt}\left(\sqrt{q_{DL}}\right) \) for identification of the linear region is derived in Appendix G. The derivative is shown for the \( s_{Ach} = 10 \) case in Fig. 6.8. This derivative is flat for the linear region.
Fig. 6.7 – Validation of Analytical Solution (Linear model, homogeneous, constant $p_{wf}$) for $s_{Ach} = 10$. The analytical solution is similar to the Laplace space solution.

Fig. 6.8 – Rate and Linear Derivative (Linear model, homogeneous, constant $p_{wf}$) for $s_{Ach} = 10$. The transient linear region is flat on the derivative while the convergence skin region gradually increases.
6.3 Dual Porosity Reservoir

The solutions\(^\text{16}\) for the closed linear dual porosity reservoir (slab matrix) for the constant rate and constant pressure inner boundary with a skin, \(s_{Ac}\) are given by Eqs. 6.17 and 6.18 respectively.

\[
\frac{p_{wDL}}{s_{\sqrt{s}}(s)} = \frac{2\pi}{s_{\sqrt{s}}(s)} \left[ \left( 1 - s_{Ac} \sqrt{s} \right) \exp \left( -2 \sqrt{s} \nu_{DFc} \right) + \left( 1 + s_{Ac} \sqrt{s} \right) \right] \frac{1}{1 - \exp \left( -2 \sqrt{s} \nu_{DFc} \right)}
\]

\[
\frac{1}{q_{DL}} = \frac{2\pi}{s_{\sqrt{s}}(s)} \left[ \left( 1 - s_{Ac} \sqrt{s} \right) \exp \left( -2 \sqrt{s} \nu_{DFc} \right) + \left( 1 + s_{Ac} \sqrt{s} \right) \right] \frac{1}{1 - \exp \left( -2 \sqrt{s} \nu_{DFc} \right)}
\]

with

\[
f(s) = \omega + \frac{\lambda_{Ac}}{3s} \frac{(1 - \omega)}{\lambda_{Ac}} \tanh \left( \frac{3(1 - \omega)\nu}{\lambda_{Ac}} \right)
\]

for the slab matrix case.

These equations are inverted from Laplace space for the constant rate and constant \(p_{wof}\) case as shown in Figs. 6.9 and 6.10. The constant rate case in Fig. 6.9 shows similar results to the homogeneous case – there are two parallel lines with an offset of \(2\pi y_{DFc}\).
Fig. 6.9 – Effect of Skin on Linear Reservoir Model (Constant rate, Dual porosity, slab matrix, infinite) for $s_{Ac} = 0$ and 10. Similar to the homogeneous case, the two responses are parallel and there is a constant offset of $2\pi(10)$ from the $s_{Ac} = 0$ case.

Fig. 6.10 – Effect of Skin on Linear Reservoir Model (Constant $p_{wf}$, Dual porosity, slab matrix, closed) for $s_{Ac} = 0$, 10 and 100. For the $s_{Ac} = 100$ case, the skin effect diminishes with time as was observed with the homogeneous case.
For the constant \( p_{wf} \) case shown in Fig. 6.10 the skin effect diminishes with time as was observed with the homogeneous case eventually approaching the linear transient response. This is also shown in Fig. 6.11. It can be observed from Fig. 6.11 that as the skin, \( s_{Ac} \), increases, the flatter initial response increases and the linear transient response of the reservoir is delayed.

An equation similar to Eq. 6.12 (for the homogeneous case) is derived in Appendix G for the slab matrix dual porosity case. From Eq. G-22,

\[
q_{DL} = \frac{1}{2\pi} y_{De} \sqrt{\frac{A_{mc}}{3}} \left[ \frac{1}{\sqrt{\pi}} I_{loc} \left( \frac{3}{A} \sqrt{D_{Ac}} \right) \right]
\]

\[\text{..........................}(6.19)\]
Where \( A = \sqrt{\frac{\lambda_{Ac}}{3} y_{De}^2 + s_{Ac}} \sqrt{\frac{\lambda_{Ac}}{3} y_{De}^3} \)

Eq. 6.19 is confirmed by comparison with the inverted Laplace space solution given in Eq. 6.18 as shown in Figs. 6.12 and 6.13 for \( s_{Ac} = 10 \) and 100 respectively. It can be observed from Fig. 6.12 that the analytical solution matches the Laplace space solutions at very early and late times. The slight difference noticed on the graph might be as a result of the assumptions made in the derivations of Eq. 6.19.

A better match with the Laplace space solutions is obtained for the \( s_{Ac} = 100 \) case in Fig. 6.13. It can thus be concluded that Eq. 6.19 is appropriate for cases with relatively higher skin, \( s_{Ac} \).

![Graph](image)

**Fig. 6.12 – Validation of Analytical Solution (Linear model, slab matrix, constant \( p_{wf} \) closed) for \( s_{Ac} = 10 \) (\( \lambda_{Ac} = 3.84 \times 10^{-4} \), \( \omega = 10^{-3} \), \( y_{De} = 0.559 \)). The analytical solution matches the Laplace space solutions at very early and late times.**
An empirical equation analogous to that for the homogeneous case previously described in Eq. 6.16 has also been found to fit the constant \( p_{wf} \) response for the dual porosity reservoir (slab matrix) shown in Fig. 6.10.

\[
\frac{1}{q_{Dlin}} = 2\pi \sqrt{\frac{m_{Dlin}}{t_{Dlin}}} + \frac{2\pi s_{cm}}{1 + 0.8\sqrt{t_{Dlin} s_{cm}}} \tag{6.20}
\]

where \( \frac{1}{q_{Dlin}} = \frac{k_m}{1422q_T} \left[ m(p_c) - m(p_{wf}) \right] \) ; \( t_{Dlin} = \frac{0.00633k_m t}{(\phi_m \mu_c)_{cm} A_m} \) and \( k_m \) is the reservoir matrix permeability.
6.4 Summary

It has been shown that the effect of skin (constant $p_{wf}$ case) on the transient response is different for radial and linear reservoirs. The effect of skin on the linear reservoir response diminishes gradually with time as demonstrated with $s_{Ac} = 0$ and $s_{Ac} = 10$ cases in Fig. 6.5. The effect of skin for the radial reservoir is the usual constant offset between parallel lines on a semilog plot. A new equation was presented to model the effect of skin on the linear reservoir. The limiting forms of the equations for homogeneous and the dual porosity (slab matrix) are compared in Table 6.1.

CHAPTER VII
APPLICATION TO SAMPLE FIELD DATA CASES

7.1 Introduction

It is necessary to predict field data with a skin effect behavior. A synthetic case is developed to represent field behavior using data given in Table 7.1. The linear model (slab matrix, constant \( p_{wf} \), closed, linear) is used to generate the transient response in dimensionless variables, \( q_{DL} \) and \( t_{DAC} \). The generated results are then converted to rate and time using Eq. 7.1.

\[
T_{q_{DL}} = \frac{k_f \sqrt{A_w} [m(p_f) - m(p_{wf})]}{1422q_{DL} T} \quad t_{DAC} = \frac{0.00633k_f t_{DAC}}{(\phi u_{ci})_{f+m} A_{cw}} \quad \text{……………..………}(7.1)
\]

The results are then plotted as Figs. 7.1 and 7.2 for the \( s_A = 0 \) and \( s_A = 10 \) cases.

The dimensionless time for the end of the convergence skin period is computed as \( 8.06 \times 10^{-4} \) using Eq. 7.2 (previously shown as Eq. 3.8). This is equivalent to a time of 0.74 days.

\[
t_{DAC} = \frac{h}{2\pi^3 L_w} \quad \text{……………..………}(7.2)
\]

The results in Figs. 7.1 and 7.2 indicate that the half-slope transient linear period (Region 4) dominates the response. Actual field data is thus expected to lie in Region 4.

Fig. 7.1 – Log-log Plot of Rate against Time (Synthetic Case \( s_{Ac} = 0 \) and 10). Arrow indicates that the convergence skin stabilizes after 0.74 days. Response is expected to be primarily in Region 4.

Fig. 7.2 – Specialized Plot of \( \frac{m(p_i) - m(p_w)}{q_g} \) against \( t^{0.5} \) (Synthetic Case \( s_{Ac} = 0 \) and 10). Arrow indicates that the convergence skin stabilizes after 0.74 days. Response is expected to be primarily in Region 4.
A preliminary procedure was presented in Chapter V for data analysis. This was for the zero skin case. The only parameter that could be determined from the \( \frac{m(pi)-m(pwf)}{q_s} \text{ vs } t^{0.5} \) plot was essentially the matrix drainage area, \( A_m \). But the techniques previously presented also apply to the case where the data points are on a straight line through the origin on the \( \frac{m(pi)-m(pwf)}{q_s} \text{ vs } t^{0.5} \) plot. It is necessary to develop techniques for the case where the data points indicate an “intercept” on the \( \frac{m(pi)-m(pwf)}{q_s} \text{ vs } t^{0.5} \) plot as expected with the presence of skin (this was demonstrated on a dimensionless plot basis in Chapter VI). In this chapter, a procedure incorporating the effect of skin will be described and the procedures will be applied to two sample field cases (Wells A and B).

### 7.2 Effect of Skin Plots

Fig. 7.3 shows a series of curves generated from the linear dual porosity model (slab matrix \( \lambda_A = 10^{-4}, \omega = 10^{-3}, s_A = 0, 1, 10, 100; y_{De} = 0.5, 1 \)). This also shown as a square root time plot in Fig. 7.4. It can be observed from Fig. 7.3 that the curves for a particular \( y_{De} \) indicate the expected initial flat portion and converge to the transient linear regime.

The plot in Fig. 7.5 clearly indicates that the Region 3 (homogeneous) equation cannot be applied for transient linear analysis since there is no half slope evident in the presence of skin.

The initial \( q_{DL} \) value of the curves in Fig. 7.3 at time zero obeys Eq. 6.12

\[
q_{DL} = \frac{1}{2 \pi A_c} \quad \text{.................................................(7.3)}
\]
Fig. 7.3 – Log-log Plot of $q_{DL}$ against $t_{DAC}$ for the Linear Dual Porosity Reservoir, Slab Matrix Case ($\lambda_{Ac} = 10^{-4}$, $\omega = 10^{-3}$, $s_{Ac} = 0, 1, 10, 100$; $y_{De} = 0.5, 1$). The curves converge to the same initial point for a fixed $s_{Ac}$. The curves also converge to the same Region 4 half-slope line for a fixed $y_{De}$.

Fig. 7.4 – Specialized Plot of $1/q_{DL}$ against $t_{DAC}^{0.5}$ for the Linear Dual Porosity Reservoir, Slab Matrix Case ($\lambda_{Ac} = 10^{-4}$, $\omega = 10^{-3}$, $s_{Ac} = 0, 1, 10, 100$; $y_{De} = 0.5, 1$). The curves converge to the same initial point for a fixed $s_{Ac}$ and asymptotically approach the $s_{Ac} = 0$ line at late times.
Fig. 7.5 – Log-log Plot of $q_{DL}$ against $t_{DAc}$ for the Linear Dual Porosity Reservoir, Slab Matrix Case ($\lambda_{Ac} = 10^{-4}$, $\omega = 10^{-3}$, $s_{Ac} = 1, 10, 100$; $y_{De} = 0.5, 1$) – Fig. 7.3 - with Homogeneous Case. This plot clearly indicates that the Region 3 (homogeneous) cannot be applied to the transient linear analysis – there is no half slope evident in the presence of skin.

The following empirical equation for the effect of skin on the dual porosity transient response (Region 4) was previously presented as Eq. 6.20

\[
\frac{1}{q_{DLm}} = 2\pi \sqrt{m_{DAcm}} + \frac{2\pi y_{Dm}}{1 + 0.8t_{DAcm}} \sqrt{\frac{1}{s_{Ac}}} \tag{7.4}
\]

where

\[
\frac{1}{q_{DLm}} = \frac{k_m}{1422q_T} \sqrt{A_m \left[ m(p_i) - m(p_w) \right]} \quad ; \quad t_{DAcm} = \frac{0.00633k_m t}{(\phi \mu c \gamma)_{Ac} A_{cm}}
\]

and $k_m$ is the reservoir matrix permeability.
Eq. 7.4 can be expressed as

\[
\frac{k_w \sqrt{A_m} \left[ m(p_i) - m(p_{\text{ref}}) \right]}{1422q_s T} = 2\pi \sqrt{\frac{0.00633k_f}{(\phi_c)_m A_m}} + \frac{2\omega_{Ac}}{s_{Ac}} \tag{7.5}
\]

where \( \left\{ \frac{m(p_i) - m(p_{\text{ref}})}{q_s} \right\}_0 \) is the intercept obtained from a plot of \( \frac{m(p_i) - m(p_{\text{ref}})}{q_s} \) vs \( \sqrt{T} \).

With \( 2\omega_{Ac} = \frac{k_w \sqrt{A_m} \left[ m(p_i) - m(p_{\text{ref}}) \right]}{1422T} \), Eq. 7.5 becomes

\[
\frac{k_w \sqrt{A_m} \left[ m(p_i) - m(p_{\text{ref}}) \right]}{1422q_s T} = 2\pi \sqrt{\frac{0.00633k_f}{(\phi_c)_m A_m}} + \frac{1}{2\pi} \frac{0.00633k_f}{(\phi_c)_m A_m} \tag{7.6}
\]

where \( \left\{ \frac{m(p_i) - m(p_{\text{ref}})}{q_s} \right\}_0 \) is the intercept obtained from a plot of \( \frac{m(p_i) - m(p_{\text{ref}})}{q_s} \) vs \( \sqrt{T} \).

\[
\frac{k_w \sqrt{A_m} \left[ m(p_i) - m(p_{\text{ref}}) \right]}{1422q_s T} = 2\pi \sqrt{\frac{0.00633k_f}{(\phi_c)_m A_m}} + \frac{2\pi(1422T)}{k_w \sqrt{A_m}} \tag{7.7}
\]

\[
\frac{k_w \sqrt{A_m} \left[ m(p_i) - m(p_{\text{ref}}) \right]}{1422q_s T} = 2\pi \sqrt{\frac{0.00633k_f}{(\phi_c)_m A_m}} + \frac{\sqrt{\frac{m(p_i) - m(p_{\text{ref}})}{q_s}} k_w \sqrt{A_m}}{1422T} + \frac{\sqrt{\frac{m(p_i) - m(p_{\text{ref}})}{q_s}} k_w \sqrt{A_m}}{0.8 \sqrt{0.00633} 2\pi(1422T) \sqrt{T}} \tag{7.8}
\]
Multiplying Eq. 7.9 by \( \frac{1422T}{k_m \sqrt{A_m}} \)

\[
\left[ \frac{m(p_i) - m(p_{of})}{q_s} \right] = \frac{1262T \sqrt{T}}{\sqrt{k_m A_m} \phi_4} + \frac{\left[ \frac{m(p_i) - m(p_{of})}{q_s} \right]^2 \left[ \frac{m(p_i) - m(p_{of})}{q_s} \right]}{\sqrt{\phi_4} \sqrt{k_m A_m}} + \frac{\left[ \frac{m(p_i) - m(p_{of})}{q_s} \right] \left[ \frac{m(p_i) - m(p_{of})}{q_s} \right]}{\sqrt{\phi_4} \sqrt{k_m A_m}} + 569T \sqrt{T}
\]

…………………………..(7.10)

The expression given by Eq. 7.10 represents an equation that can be used to fit data on a plot of \( \frac{m(p_i) - m(p_{of})}{q_s} \) vs. \( \sqrt{T} \). The term \( \sqrt{k_m A_m} \) can be determined from the equation previously presented for Region 4 in Chapter IV.

\[
\sqrt{k_m A_m} = \frac{1262T}{\sqrt{\phi_4} m_4} \frac{1}{m_4}
\]

………………………………..(7.11)

\( m_4 \) is the slope of a line drawn through the origin passing through the linear half-slope data points.

Eq. 7.10 can be reproduced on a log-log plot using Eq. 7.12.

\[
q_s = \left[ \frac{m(p_i) - m(p_{of})}{q_s} \right] \sqrt{\frac{1262T \sqrt{T}}{\sqrt{k_m A_m} \phi_4} + \frac{\left[ \frac{m(p_i) - m(p_{of})}{q_s} \right]^2 \left[ \frac{m(p_i) - m(p_{of})}{q_s} \right]}{\sqrt{\phi_4} \sqrt{k_m A_m}} + \frac{\left[ \frac{m(p_i) - m(p_{of})}{q_s} \right] \left[ \frac{m(p_i) - m(p_{of})}{q_s} \right]}{\sqrt{\phi_4} \sqrt{k_m A_m}} + 569T \sqrt{T}}
\]

………………………………..(7.12)
The procedure previously given in Chapter V can be summarized and modified thus:

a) Obtain field production rate data.

b) Check for half slope on log-log plot of rate against time indicating the transient linear flow regime. Also check for a straight line on a plot of \( \frac{[m(p_i)-m(p_{wi})]}{q_{g}} \) against \( t^{0.5} \).

c) Draw a line through the origin passing through the linear half-slope data points. Determine the slope of this line and use as \( \bar{m}_4 \) in Eq. 7.11 to determine \( \sqrt{k_m A_{cm}} \).

d) If matrix permeability, \( k_m \) is known then calculate matrix drainage area \( A_{cm} \) from

\[ \sqrt{k_m A_{cm}} \]

e) Use \( \sqrt{k_m A_{cm}} \) and the intercept \( \left( \frac{[m(p_i)-m(p_{wi})]}{q_{g}} \right)_0 \) in Eq. 7.10 to fit the given field data.

f) Reproduce the equivalent to the fit from step e) on the log-log plot using Eq. 7.12.

### 7.3 Application of Procedure to Field Data

In this section, the methods previously presented will be applied to actual field cases. Two examples are presented (Wells A and B). The gas rate and flowing tubing pressure data are shown for Wells A and B in Figs. 7.6 and 7.7 respectively. The reservoir and fluid properties data are shown in Table 7.2. Other computed parameters are given in Table 7.3. The length of the wells are shown in Table 7.4 A log-log plot of the rate
against time and specialized plot of \( \frac{[m(p_i)-m(p_{wf})]}{q_g} \) against \( t^{0.5} \) is shown for Well A in Figs. 7.8 and 7.9. These plots are shown for Well B in Figs. 7.10 and 7.11. These plots indicate the transient linear flow (half-slope on log-log plot). The log-log plot also indicates the constant \( p_{wf} \) effect of skin previously described. An initial curve corresponding to the convergence skin effect is noticed at early times. The transient linear is noticed at later times.

Fig. 7.12 – Specialized Plot of \(\frac{m(p_i)-m(p_{wf})}{q_g}\) against \(t^{0.5}\) with Eq. 7.10 Fit for Well A. Line shown is drawn through origin and fitted to data. Eq. 7.10 is also fitted to data as shown. A better fit can be obtained by choosing a lower intercept.

Fig. 7.13 – Log-log Plot Representation of Fig.7.12 Fit for Well A. Eq. 7.12 is also fitted to data as shown.
7.4 Discussion

A sample calculation for the matrix drainage area, $A_{cm}$ using the techniques described in
Chapter V is described for Well A. The slope is determined from Fig. 7.9 and 7.12 as
35,874 respectively. It should be noted that the slope computed is that of a line drawn
through the origin as shown in Fig. 7.9 and 7.12. The intercept on the y-axis is
determined approximately as 116,875.

Eq. 7.10 is fitted to that data and shown in Fig 7.12. The plot from Fig. 7.12 is
reproduced on a log-log plot using Eq. 7.12 and shown in Fig. 7.13.

The parameter $\sqrt{k_m A_{cm}}$ can be calculated using Eq. 7.11.

$$\sqrt{k_m A_{cm}} = \frac{1262T}{\sqrt{(\partial \mu c_f)_{f_{\text{sm}} m_4}}} = \frac{1262(635)}{\sqrt{(0.034)(0.0199)(3.03*10^{-4})(36,040)}} = 4.93 \times 10^4 \text{md}^{0.5} \text{ft}^2$$

And

$$A_{cm} = \frac{1}{\sqrt{k_m}} = \frac{1}{1.5 \times 10^{-4}} = 4.03 \times 10^6 \text{ ft}^2$$

$A_{cm}$ is computed similarly for Well B as $7.54 \times 10^6 \text{ ft}^2$. Well B has a larger $A_{cm}$ value than
Well A. This indicates that Well B has a larger matrix area contacted by the frac job.

Other information is required to determine the fracture spacing from $A_{cm}$ as
demonstrated in Chapter V. Computed spacing for the slab matrix case can then be used
to determine the corresponding values for other column and cube matrix geometries as
described in Chapter V. The fracture spacings will be in the ratios 1:2:3 for the same
matrix drainage area, $A_{cm}$.

In conclusion, a procedure has been presented for analyzing field data in which
transient linear flow has been observed. This procedure is dependent on the linear model
presented in this paper with its underlying assumptions and ability to reasonably
determine fluid and reservoir properties. The well has also been assumed to be located in the center of the reservoir.

It is concluded that field data obtain exhibit Region 4 only (drainage primarily from the matrix). The only parameter than can be determined from available data is \( \sqrt{k_m A_m} \).

The effects of adsorption have been neglected for reasons mentioned in Chapter I. As pressures approach 1000 psia in the Barnett shale, these effects will become more prominent.

The effect of water production has also been neglected. These are areas of further research.
CHAPTER VIII
CONCLUSIONS AND RECOMMENDATIONS

8.1 Conclusions

The major conclusions of this work can be summarized as follows:

1. A linear dual porosity model can be utilized to represent multi-fractured horizontal wells in shale gas reservoirs.

2. It has been shown extensively that matrix drainage of any geometry at constant pressure boundary conditions results in transient linear flow.

3. Five flow regions were identified using this linear model. Region 1 is the early transient linear response in the fracture system. Region 2 is the bilinear flow regime and occurs when there is a transient linear in the fracture and matrix simultaneously. Region 3 is the response for a homogeneous reservoir case. Region 4 is primarily drainage of the matrix (our regime of interest). Region 5 occurs when all the boundaries start to influence the transient response.

4. New analysis equations were presented for Regions 1 to 4.

5. The effect of skin on the response for the constant rate case is different from that for the constant $p_{wf}$ case. The effect of skin shows up as parallel lines with a constant offset for the constant rate case while it diminishes with time for the constant $p_{wf}$ case.
6. A new analytical equation was presented to model the constant $p_{wf}$ effect of skin in a linear reservoir.

7. Different shape factor formulations result in similar Region 4 response when appropriate $f(s)$ modifications consistent with $\lambda_{Ac}$ computations are made.

8. Different matrix geometry exhibit the same Region 4 response when the area-volume ratios are made equivalent.

8.2 Recommendations for Future Work

The following recommendations are listed:

1. Investigation of the effect of water production on the results.

2. Investigation of the effects of adsorption and desorption

3. Investigation of the effects of anisotropy and varying well location.

APPENDIX A

SINGLE MATRIX BLOCK DRAINAGE
AT CONSTANT PRESSURE

A-1 Overview

As previously described, the dual porosity model of a naturally fractured reservoir is composed of matrix blocks draining into surrounding fractures at constant pressure (the most widely used boundary condition in the literature). It was mentioned in Chapter I that the drainage of these matrix blocks is the cause of the transient linear regime observed in the shale gas wells. In this section, drainage of single matrix blocks will be investigated. Three methods will be used to illustrate and compare constant pressure drainage of matrix blocks of different geometries – slab, cylinder and sphere. The cylinder and sphere geometries have been used in the literature as approximations to the ideal two-dimensional (column) and three-dimensional (cube) geometries. This will be demonstrated for the slightly compressible fluid case. The results are expected to be applicable to the compressible gas case. These methods are numerical simulation, analytical solution and Laplace space solutions. The development of the equations for the analytical and Laplace space solutions are shown only for the slab case in Section A-2. Data common to three matrix geometries is shown in Table A-1.
A-10 SLAB MATRIX

Data specific to the slab case is shown in Table A-2. A schematic of the slab matrix is shown in Fig. A-1. The three methods will subsequently be presented.

A-10.1 Numerical Simulation

The simulation was conducted using two numerical simulators – GASSIM and ECLIPSE version 2007.1 (Schlumberger). A 101 x 1 x 1 grid system was utilized in both simulators with \( \Delta x = 0.5 \) ft, \( \Delta y = 1000 \) ft and \( \Delta z = 10 \) ft. The 101\textsuperscript{st} grid contains the well (constant bottomhole pressure of 100 psi) and was assigned a small porosity of \( 10^{-8} \) and high permeability of \( 10^{11} \) md to model the constant pressure condition at the boundary of the slab. It was found by comparing with the analytical solution that maximum timestep sizes of 0.05 (GASSIM) and 0.001(ECLIPSE) were required to give accurate results.

Fig. A-1 – Schematic of Slab Matrix.
A-10.2 Analytical Solution

The development of the equations for the slab matrix case is illustrated in Appendix A-2.

The two equations used are:

\[ q = \frac{V_{\text{lim}} \phi_c}{l^2} \left( \sum_{n=0}^{\infty} e^{-\frac{\alpha(2n+1)^2 \pi^2}{4l^2}} \right) \] (Method I) \hspace{1cm} (A-1)

\[ q = -0.00633 \frac{k_m A_{\text{cm}}}{\mu} \frac{2}{l^2} (p_f - p_i) \left( \sum_{n=0}^{\infty} (-1)^n e^{-\frac{\alpha(2n+1)^2 \pi^2}{4l^2}} \right) \sin \left( \frac{(2n+1)\pi}{2} \right) \] (Method II) \hspace{1cm} (A-2)

Where \( \alpha \) is the hydraulic diffusivity defined in Appendix A as

\[ \alpha = \frac{0.00633k_m}{\phi \mu k_i} \]

A-10.3 Laplace Space Solution

The development of the equation for the slab matrix case is illustrated in Appendix A-2.

The equation is given by

\[ q = -0.00633 \frac{k_m A_{\text{cm}}}{\mu} \left[ \frac{d}{dz} \left. p_m \right|_{z=L/2} \right] \] \hspace{1cm} (A-3)

where \( \left. \frac{d}{dz} p_m \right|_{z=L/2} = \frac{2}{L} \sqrt{s} \left( \frac{p_f - p_i}{s} \right) \tanh \sqrt{s} \) \hspace{1cm} and is inverted numerically using a Laplace space inversion algorithm and substituted into Eq. A.3.

The results from all the tests are shown in Fig. A-2. It can be observed from Fig. A-2 that the results from all the methods are similar and exhibit an initial transient linear
response (one-half slope on a log-log plot) and a boundary-dominated response at later times.

![Graph showing comparison of drainage results](image)

**Fig. A-2 – Comparison of Slab Matrix Drainage Results.** All methods exhibit similar initial transient linear response and later boundary dominated response.

### A-11 CYLINDER MATRIX

Data specific to the cylinder case is shown in Table A-3. The three methods will subsequently be presented.

#### A-11.1 Numerical Simulation

The simulation was conducted using two numerical simulators – *GASSIM* and *ECLIPSE* version 2007.1 (Schlumberger). A 101 x 1 radial grid system ($\Delta r = 1$ ft, $\Delta z = 1$ ft) was utilized in *GASSIM* while a 201 x 1 radial grid ($\Delta r = 0.5$ ft, $\Delta z = 1$ ft) was utilized in
**ECLIPSE.** The 101st and 201st grid in GASSIM and ECLIPSE respectively contain the well (constant bottomhole pressure of 100 psi) and was assigned a small porosity of $10^{-4}$ and high permeability of $10^6$ md to model the constant pressure condition at the boundary of the slab. It was found by comparing with the analytical solution that maximum timestep sizes of 0.05 (GASSIM) and 0.01 (ECLIPSE) were required to give accurate results.

| Table A-3 – Data for the Cylinder Matrix Case. |
|-----------------|-----------------|
| $r_{mc}$        | 100 ft          |
| $p_f$           | 100 psi         |
| $p_i$           | 1000 psi        |
| $V_{pm}$        | 2,042 ft³       |
| $h$             | 1 ft            |
| $A_{cm}$        | 628 ft²         |

### A-11.2 Analytical Solution

The two equations developed using methods similar to the slab matrix case are:

$$q = \frac{V_{mc} \phi c_t}{B} \left[ \alpha (p_i - p_f) \frac{4}{r_{mc}^2} \sum_{n=1}^{\infty} e^{-\alpha x_i^2} \right]$$

(Method I) …………(A-4)

$$q = -0.00633 \frac{k_m A_{cm}}{\mu} (p_f - p_i) \frac{2}{r_{mc}} \sum_{n=1}^{\infty} e^{-\alpha x_i^2}$$

(Method II) …………(A-5)

Where $\alpha$ is the hydraulic diffusivity defined in Appendix A as
\[ \alpha = \frac{0.00633 k_m}{\phi \mu \alpha_0} \]

and \( \alpha_n \) is the \( n \)th zero of the Bessel function \( J_0 \)

### A-11.3 Laplace Space Solution

The equation developed using methods similar to the slab matrix case is given by

\[ q = -0.00633 \frac{k_m A_{cm}}{\mu} \varepsilon^{-1} \left[ \frac{d \rho_m}{d r} \right]_{r=r_{nc}} \]  

……………………………(A-6)

where \( \left[ \frac{d \rho_m}{d r} \right]_{r=r_{nc}} = \sqrt{s} \left( \frac{p - p_i}{s} \right) I_1 \sqrt{s} \) and is inverted numerically using a Laplace space inversion algorithm and substituted into Eq. A-6.

\( I_0, I_1 \) are modified Bessel functions.

The results from all the tests are shown in Fig. A-3. It can be observed from Fig. A-3 that the results from all the methods are similar and exhibit an initial transient linear response (one-half slope on a log-log plot) and a boundary-dominated response at later times.
Fig. A-3 – Comparison of Cylinder Matrix Drainage Results. All methods exhibit similar initial transient linear response and later boundary dominated response

A-12 SPHERE MATRIX

Data specific to the sphere case is shown in Table A-4. The three methods will subsequently be presented.

A-12.1 Numerical Simulation

There is no available simulator for the sphere case. An attempt will be made to simulate the sphere matrix case using the numerical simulator GASSIM. The cylinder case will be adapted to simulate the sphere case by using fictitious transmissibilities and porosity.

Our equation for the required pore volume (grid) of a sphere is given by

\[ V_{pm} = \frac{4}{3} \pi (r_2^3 - r_1^3) \mu \phi \]

………………………………………(A-7)
Where $\phi = 0.065$ as given in Table A-1

$r_1$ and $r_2$ are inner and outer radial grid dimensions

The equation for the pore volume (grid) of a cylinder is thus given by

$$V_{pm} = \pi \left( r_2^2 - r_1^2 \right) h \phi_s$$

……………………………………(A-8)

$\phi_s$ is a fictitious porosity that will be input into the simulator (cylinder case) to yield the required sphere pore volume.

The transmissibility of the sphere (grid) is given by

$$T_1 = 0.00633 \frac{r_1 r_2 4 \pi k}{r_2 - r_1}$$

……………………………………(A-9)

The transmissibility of the cylinder (grid) is thus given by

$$T_2 = \left( 0.00633 \right) \frac{2 \pi}{\ln \left( \frac{r_2}{r_1} \right)} \frac{hk_s}{\ln \left( \frac{r_2}{r_1} \right)}$$

……………………………………(A-10)

$k_s$ is a fictitious permeability that will be input into the simulator (cylinder case) to behave like the sphere.

A 101 x 1 radial grid system ($\Delta r = 1$ ft, $\Delta z = 10$ ft) was utilized.

A-12.2 Analytical Solution

The two equations developed using methods similar to the slab matrix case are

$$ q = \frac{V_{lm} \phi_i}{B} \left[ \sum_{n=1}^{\infty} \frac{1}{n^2} e^{-\frac{\alpha n^2 \pi^2}{r_{ms}^2}} \right] $$  \hspace{1cm} (Method I) \hspace{1cm} (A-11)

$$ q = -0.00633 \frac{k_m A_{cm}}{\mu} \left( \frac{p_f - p_i}{1000} \right) \left[ \sum_{n=1}^{\infty} \frac{(-1)^n}{n} e^{-\frac{\alpha n^2 \pi^2}{r_{ms}^2}} \right] \hspace{1cm} (Method II) \hspace{1cm} (A-12) $$

A-12.3 Laplace Space Solution

The equation developed using methods similar to the slab matrix case are

$$ q = -0.00633 \frac{k_m A_{cm}}{\mu} \left[ \frac{d}{dz} \left. \left( \frac{dp_m}{dr} \right) \right|_{r=r_{ms}} \right] \hspace{1cm} \cdots (A-13) $$

where

$$ \left. \frac{d}{dz} \left( \frac{dp_m}{dr} \right) \right|_{r=r_{ms}} = \frac{1}{r_{ms}} \left( \frac{p_f - p_i}{s} \right) \left[ \sqrt{s \coth(s)} - 1 \right] $$

and is inverted numerically using a Laplace space inversion algorithm and substituted into Eq. A-13.
The results from all the tests are shown in Fig. A-4. It can be observed from Fig. A-4 that the results from Analytical methods and Laplace exhibit similar initial transient linear response. Numerical simulation is not similar to the other methods. It is possible that a match with the other methods might be obtained with a smaller maximum timestep (0.05 days was used in this work) and smaller grids.

Fig. A-4 – Comparison of Sphere Matrix Drainage Results. Analytical and Laplace space solutions exhibit similar response. Numerical simulation is different probably due to approximations.
Summary

Matrix drainage at constant pressure was investigated using different methods. It can be concluded from Figs. A-2 to A-4 that drainage of matrix blocks of any geometry at constant pressure boundary condition results in transient linear flow (one-half slope on a log-log plot). This is one of the possible causes of the observed transient linear flow regime in the shale gas wells as discussed in Chapter I.

A-2 Derivation of Equations for Slab Matrix Case

In this section, the development of an equation for one–dimensional slab geometry matrix drainage at constant pressure is shown using analogy with heat flow principles from Carslaw and Jaeger.\(^7\)

The underlying assumptions are stated thus:

- Incompressible fluid
- Constant fluid properties
- The slab is initially at the same initial pressure
- One boundary is at constant pressure

A-20 Analytical solution (Method I)

Half of the slab is modeled. The length of which is given by

\[ l = \frac{L}{2} \]

The following expression can be written for the pressure distribution

\[
\frac{p - p_i}{p_f - p_i} = \frac{8}{\pi^2} \sum_{n=0}^{\infty} \frac{1}{(2n+1)^2} \frac{a(2n+1)^2 \pi^2}{4l^2} \]

………………………………(A-14)
where \( p_f \) is the constant pressure boundary condition, \( \bar{p} \) is the average pressure and \( p_i \) is the initial pressure

and \( \alpha = \frac{0.00633\kappa_m}{\phi \mu \kappa_i} \)

From Eq. A-14,

\[
\bar{p} = p_i + (p_f - p_i) \sum_{n=0}^{\infty} \frac{1}{\pi^2} \frac{\alpha(2n+1)^2 \pi^2}{4l^2}
\]

.............................(A-15)

The fluid content at any time is given by

\[
Q = \frac{V_{\text{in}} \phi \kappa_i \bar{p}}{B}
\]

differentiating Eq. A-16

\[
\frac{dQ}{dt} = \frac{V_{\text{in}} \phi \kappa_i \frac{d\bar{p}}{dt}}{B}
\]

differentiating Eq. A-15

\[
\frac{d\bar{p}}{dt} = -\frac{2}{l^2} (p_f - p_i) \sum_{n=0}^{\infty} \frac{\alpha(2n+1)^2 \pi^2}{4l^2}
\]

.............................(A-18)

Substituting Eq. A-18 in Eq. A-17

\[
\frac{dQ}{dt} = \frac{V_{\text{in}} \phi \kappa_i}{B} \frac{2\alpha}{l^2} (p_f - p_i) \sum_{n=0}^{\infty} \frac{\alpha(2n+1)^2 \pi^2}{4l^2}
\]

.............................(A-19)

And thus rate (scf/day) is given by

\[
q = \frac{dQ}{dt}
\]

\[
q = \frac{V_{\text{in}} \phi \kappa_i}{B} \frac{2\alpha}{l^2} (p_f - p_i) \sum_{n=0}^{\infty} \frac{\alpha(2n+1)^2 \pi^2}{4l^2}
\]

.............................(A-20)

**A-21 Analytical solution (Method II)**

The following expression can also be written for the pressure distribution

\[
\frac{p - p_i}{p_f - p_i} = 1 - \frac{4}{\pi} \sum_{n=0}^{\infty} \frac{(-1)^n}{2n+1} \frac{\alpha(2n+1)^2 \pi^2}{4l^2} \cos \left( \frac{(2n+1)}{2l} \pi \right)
\]

.............................(A-21)
\[ p = (p_f - p_i) - (p_f - p_i) \frac{4}{\pi} \sum_{n=0}^{\infty} \left( \frac{(-1)^n}{2n+1} \right) e^{-\frac{\alpha(2n+1)^2 \pi^2 l}{4l^2}} \cos \left[ \frac{(2n+1)\pi}{2l} \right] + p_i \]

.................................(A-22)

Differentiating Eq. A-22

\[
\frac{\partial p}{\partial x} = \frac{(2n+1)\pi}{2l} \left( p_f - p_i \right) \frac{4}{\pi} \sum_{n=0}^{\infty} \left( \frac{(-1)^n}{2n+1} \right) e^{-\frac{\alpha(2n+1)^2 \pi^2 l}{4l^2}} \sin \left[ \frac{(2n+1)\pi}{2l} \right]
\]

.................................(A-23)

\[
\frac{\partial p}{\partial x}_{|_{x=l}} = \frac{(2n+1)\pi}{2l} \left( p_f - p_i \right) \frac{4}{\pi} \sum_{n=0}^{\infty} \left( \frac{(-1)^n}{2n+1} \right) e^{-\frac{\alpha(2n+1)^2 \pi^2 l}{4l^2}} \sin \left[ \frac{(2n+1)\pi}{2l} \right]
\]

.................................(A-24)

\[
\frac{\partial p}{\partial x}_{|_{x=l}} = \frac{2}{l} \left( p_f - p_i \right) \sum_{n=0}^{\infty} (-1)^n e^{-\frac{\alpha(2n+1)^2 \pi^2 l}{4l^2}} \sin \left[ \frac{(2n+1)\pi}{2l} \right]
\]

.................................(A-25)

\[
\frac{q}{A_{cm}} = -0.00633 \frac{k_m}{\mu} \left[ \frac{\partial p}{\partial x} \right]_{|_{x=l}}
\]

.................................(A-26)

Thus rate is given by

\[
q = -0.00633 \frac{k_m A_{cm}}{\mu} \frac{2}{l} \left( p_f - p_i \right) \sum_{n=0}^{\infty} (-1)^n e^{-\frac{\alpha(2n+1)^2 \pi^2 l}{4l^2}} \sin \left[ \frac{(2n+1)\pi}{2l} \right]
\]

.................................(A-27)

**A-22 Laplace Space Solution**

This method utilizes a form of the matrix-fracture source term normally utilized in the dual porosity equations.

The following dimensionless variable definitions are used.

\[
p_D = \frac{k_h (p_i - p)}{141.2qB\mu}
\]

\[
t_{DL} = 0.00633 \frac{k_m t}{\phi u c \left( \frac{L}{2} \right)^2}
\]

\[
z_D = \frac{z}{L/2}
\]

.................................(A-28)
The diffusivity equations for the matrix and fracture and the boundary conditions are stated below:

\[
\frac{\partial^2 p_m}{\partial z^2} = \left( \frac{\partial \psi_i}{k} \right) \frac{\partial p_m}{\partial t} \quad \text{........................................... (A-29)}
\]

Initial condition: \( p_m(z,0) = p_i \)

Inner boundary: at \( z = 0, \frac{\partial p_m}{\partial z} = 0 \) (line of symmetry)

Outer boundary: at \( z = \frac{L}{2}, p_n = p_f \)

Converting Eq. A-29 to dimensionless variables

\[
\frac{\partial^2 p_{Dm}}{\partial \xi^2} = \frac{\partial p_{Dm}}{\partial \eta} \quad \text{........................................... (A-29)}
\]

The Initial condition in Eq. A-29 becomes in dimensionless variables

\( p_{Dm}(\xi,0) = 0 \)  
\( \text{........................................... (A-30)} \)

The Inner boundary condition in Eq. A-29 becomes in dimensionless variables

\[ \left. \frac{\partial p_{Dm}}{\partial \xi} \right|_{\xi=0} = 0 \]  
\( \text{........................................... (A-31)} \)

The outer boundary condition in Eq. A-29 becomes in dimensionless variables

\( \left. p_{Dm} \right|_{\xi=1} = p_{Df} \)  
\( \text{........................................... (A-32)} \)

\[
\frac{d^2 p_{Dm}}{d \xi^2} \left[ \tilde{p}_{Dm} - p_{Dm}(\xi,0) \right] = 0 \quad \text{........................................... (A-33)}
\]

Initial condition: \( \tilde{p}_{Dm}(\xi,0) = 0 \)

Inner boundary: \( \left. \frac{d p_{Dm}}{d \xi} \right|_{\xi=0} = 0 \)

Outer boundary: \( \left. p_{Dm} \right|_{\xi=1} = p_{Df} \)

The general solution is given by

\[
\tilde{p}_{Dm} = A \cosh \sqrt{s} \xi + B \sinh \sqrt{s} \xi \quad \text{........................................... (A-34)}
\]

and \( A \) and \( B \) are determined as

\[
A = \frac{p_{Df}}{\cosh \sqrt{s}}
\]
and Eq. A-34 becomes \[ \frac{p_{Dm}}{p_{Df}} = \frac{\cosh \sqrt{s} z_D}{\cosh \sqrt{s}} \] .................................(A-35)

Transforming Eq. A-35:

\[
\frac{p_m}{s} = p_i + \left( \frac{p_f - p_i}{s} \right) \left( \frac{\cosh \sqrt{s} \frac{z}{L/2}}{\cosh \sqrt{s}} \right) \]

.................................(A-36)

\[
\frac{dp_m}{dz} = \frac{2}{L} \sqrt{s} \left( \frac{p_f - p_i}{s} \right) \frac{\sinh \sqrt{s} \frac{z}{L/2}}{\cosh \sqrt{s}} \]

.................................(A-37)

\[
\left. \frac{dp_m}{dz} \right|_{z = L/2} = \frac{2}{L} \sqrt{s} \left( \frac{p_f - p_i}{s} \right) \tanh \sqrt{s} \]

.................................(A-38)

Eq. A-38 is inverted using the Stehfest algorithm. It should be noted that the inverse of the Laplace variable, \( s \) is the dimensionless variable \( t_{DL} \). This is then converted to time, \( t \) using the dimensionless variable definitions in Eq. A-28.

\[
q = -0.00633 \frac{k_mA_{cm}}{\mu} \left[ \frac{dp_m}{dz} \right]_{z = L/2} \]

.................................(A-39)
APPENDIX B
LINEAR DUAL POROSITY MODEL

Derivations for the linear dual porosity model (slab matrix, constant rate, bounded rectangular reservoir) are shown in this section. The assumptions relevant to the model are stated:

Naturally fractured reservoir is made up of matrix and fractures (dual-porosity)
Both porous media are homogeneous and isotropic
Matrix acts as a uniformly distributed source for the fractures
Fluid flows through the fractures to the wellbore
Flow of a slightly compressible fluid of constant viscosity
Reservoir is a bounded rectangular reservoir with a well at the centre producing at constant rate

The following dimensionless variables are defined

Dimensionless time: \[ t_{Da} = \frac{0.00633k_f r_f}{D_{Ac} A_{cm} \mu \phi} \]
Dimensionless pressure: \[ p_{dl} = \frac{k_f \sqrt{A_{cm} (p_s - p)}}{141.2qB\mu} \]
Storativity: \[ \omega = \frac{[\phi_i]}{[\phi_i]_{w} + [\phi_i]_{f}} \]
Interporosity flow parameter: \[ \lambda_m = \frac{A_m}{k_f} \]
Dimensionless length coordinate: \[ z_D = \frac{z}{L/2} \] ..................................(B-1)
The diffusivity equations for the matrix and fracture along with the boundary conditions are stated below:

**Matrix**

$$\frac{\partial^2 p_m}{\partial z^2} = \left( \frac{\phi \mu c_r}{k} \right)_m \frac{\partial p_m}{\partial t} \tag{B-2}$$

Initial condition: \( p_m(z,0) = p_i \)

Inner boundary: At \( z = 0, \frac{\partial p_m}{\partial z} = 0 \) (line of symmetry)

Outer boundary: At \( z = \frac{L}{2}, p_m = p_f \)

**Fractures**

$$\frac{\partial^2 p_f}{\partial y^2} = \left( \frac{\phi c_r}{k} \right)_f \frac{\partial p_f}{\partial t} - \frac{k_r}{k_f L_f^2} \frac{\partial p_m}{\partial z} \bigg|_{z = \frac{L_f}{2}} \tag{B-3}$$

The additional term on the right-hand side is the source term from the matrix.

Initial condition: \( p_f(y,0) = p_i \)

Inner boundary: \( q = -\frac{k_f A_m}{\mu} \left( \frac{\partial p_f}{\partial y} \right)_{y=0} \) (constant rate)

Outer boundary: At \( y = \frac{y}{\sqrt{\lambda_m}}, \frac{\partial p_f}{\partial y} = 0 \) (no-flow boundary)

Converting Eq. B-2 to dimensionless variables with definitions in Eq. B-1

$$\frac{\partial^2 p_{Dlm}}{\partial z_{D}^2} = (1-\omega) \frac{L^2}{k_f} \frac{1}{4 k_m A_m} \frac{\partial p_{Dlm}}{\partial t_{DAc}}$$

and

$$\frac{\partial^2 p_{Dlm}}{\partial z_{D}^2} = \frac{3}{\lambda_{Ac}} (1-\omega) \frac{\partial p_{Dm}}{\partial t_{DAc}} \tag{B-4}$$

where \( \lambda_{Ac} = \frac{12 k_m}{L^2 k_f} A_{cv} \) is the Warren and Root interporosity flow parameter
The Initial condition in Eq. B-2 becomes in dimensionless variables
\[ p_{DLm}(z_D,0) = 0 \] ..............................(B-5)

The Inner boundary condition in Eq. B-2 becomes in dimensionless variables
\[ \left. \frac{\partial p_{DLm}}{\partial z} \right|_{z_0=0} = 0 \] ..............................(B-6)

The outer boundary condition in Eqn. B-2 becomes in dimensionless variables
\[ \left. p_{DLm} \right|_{z_0=1} = p_{DLf} \] ..............................(B-7)

Transforming Eqs. B-4, B-5, B-6 and B-7 into Laplace space
\[ \frac{d^2 p_{DLm}}{dz_D^2} + \frac{3(1-\omega)}{\lambda_c} p_{DLm}(z_D,0) = 0 \] ..............................(B-8)

initial condition: \( p_{DLm}(z_D,0) = 0 \)
inner boundary: \( \left. \frac{d p_{DLm}}{dz_D} \right|_{z_0=0} = 0 \)
outer boundary: \( \left. p_{DLm} \right|_{z_0=1} = p_{DLf} \)

Applying the initial condition to Eq. B-8 yields
\[ \frac{d^2 p_{DLm}}{dz_D^2} + \frac{3(1-\omega)}{\lambda_c} p_{DLm} = 0 \] ..............................(B-9)

the general solution is given by
\[ p_{DLm} = A \cosh \left( \frac{3(1-\omega)s}{\lambda_c} z_D \right) + B \sinh \left( \frac{3(1-\omega)s}{\lambda_c} z_D \right) \] ..............................(B-10)

A and B are determined as

\[ B = 0 \]

\[ A = \frac{p_{DLf}}{\cosh \left( \frac{3(1-\omega)s}{\lambda_c} z_D \right)} \]

and Eq. B-10 becomes
\[ \frac{p_{DLm}}{p_{DLf}} = \frac{\cosh \left( \frac{3(1-\omega)s}{\lambda_c} z_D \right)}{\cosh \left( \frac{3(1-\omega)s}{\lambda_c} \right)} \] ..............................(B-11)
Converting the equation for the fractures in Eqn. B-3 into dimensionless variables

\[
\frac{\partial^2 P_{D_{L_{f}}}}{\partial y_D^2} = \alpha \left[ \frac{\partial p_{D_{L_{f}}}}{\partial y_D} - \frac{\lambda_{m}}{3} \frac{\partial p_{D_{L_{f}}}}{\partial z_D} \right] \bigg|_{z_D=1} \quad \text{(B-12)}
\]

Initial condition: \( p_{D_{L_{f}}} (y_D, 0) = 0 \)

Inner boundary: \( \left. \frac{\partial p_{D_{L_{f}}}}{\partial y_D} \right|_{y_D=0} = -2\pi \)

Outer boundary: \( \left. \frac{\partial p_{D_{L_{f}}}}{\partial y_D} \left( \sqrt{\frac{\lambda_{c}}{t_{D_{m}}}} \right) \right| = 0 \)

Transforming Eqn. B-12 into Laplace space

\[
\frac{d^2 P_{D_{L_{f}}}}{dy_D^2} = \alpha \left[ \frac{P_{D_{L_{f}}}}{y_D} + \frac{\lambda_{m}}{3} \right] \sqrt{\frac{3(1-\omega)s}{\lambda_{c}}} \tan \left( \frac{3(1-\omega)s}{\lambda_{c}} \right) \quad \text{(B-13)}
\]

Differentiating and substituting Eqn. B-11 into B-13

\[
\frac{d^2 P_{D_{L_{f}}}}{dy_D^2} = \alpha \left[ \frac{P_{D_{L_{f}}}}{y_D} + \frac{\lambda_{m}}{3} \right] \sqrt{\frac{3(1-\omega)s}{\lambda_{c}}} \tan \left( \frac{3(1-\omega)s}{\lambda_{c}} \right) = 0
\]

Which can be represented as

\[
\frac{d^2 P_{D_{L_{f}}}}{dy_D^2} - p_{D_{L_{f}}} s f(s) = 0 \quad \text{(B-14)}
\]

where  \( f(s) = \omega + \sqrt{\frac{3(1-\omega)s}{\lambda_{c}}} \)

Eq. B-12 thus becomes in Laplace space

\[
\frac{d^2 P_{D_{L_{f}}}}{dy_D^2} - s f(s) P_{D_{L_{f}}} = 0 \quad \text{(B-15)}
\]

Initial condition: \( P_{D_{L_{f}}} (y_D, 0) = 0 \)

Inner boundary: \( \left. \frac{d P_{D_{L_{f}}}}{dy_D} \right|_{y_D=0} = \frac{2\pi}{s} \)
Outer boundary: \[ \frac{dP_{DL}}{dy_D} \left( \frac{y_D}{\sqrt{A_w}} \right) = 0 \]

Thus, the general solution to Eq. B-15 is

\[ P_{DL} = A \cosh\left( \sqrt{sf'(s)y_D} \right) + B \sinh\left( \sqrt{sf'(s)y_D} \right) \]  
.................................(B-16)

A and B are determined as

\[ B = \frac{-2\pi}{s\sqrt{sf'(s)}} \]  
.................................(B-17)

\[ A = \frac{2\pi}{s\sqrt{sf'(s)}} \frac{s\cosh\left( \sqrt{sf'(s)y_D} / \sqrt{A_w} \right)}{\sinh\left( \sqrt{sf'(s)y_D} / \sqrt{A_w} \right)} \]

Substituting into Eqn. B-16 yields

\[ P_{DL} = \frac{2\pi}{s\sqrt{sf'(s)}} \cosh\left( \sqrt{sf'(s)y_D} / \sqrt{A_w} \right) \frac{s\cosh\left( \sqrt{sf'(s)y_D} / \sqrt{A_w} \right)}{\sinh\left( \sqrt{sf'(s)y_D} / \sqrt{A_w} \right)} - \frac{2\pi}{s\sqrt{sf'(s)}} \sinh\left( \sqrt{sf'(s)y_D} / \sqrt{A_w} \right) \]  
.................................(B-18)

Substituting \( y_D = 0 \) (at the well) into Eq B-18 yields

\[ P_{DL} = \frac{2\pi}{s\sqrt{sf'(s)}} \cosh\left( \sqrt{sf'(s)y_D} / \sqrt{A_w} \right) \]  
.................................(B-19)

and \[ P_{DL} = \frac{2\pi}{s\sqrt{sf'(s)}} \frac{e^{\sqrt{sf'(s)y_D} / \sqrt{A_w}}} {e^{\sqrt{sf'(s)y_D} / \sqrt{A_w}}} + \frac{e^{-\sqrt{sf'(s)y_D} / \sqrt{A_w}}} {e^{-\sqrt{sf'(s)y_D} / \sqrt{A_w}}} \]  
.................................(B-20)

\[ P_{DL} = \frac{2\pi}{s\sqrt{sf'(s)}} \left[ e^{\sqrt{sf'(s)y_D}} + e^{-\sqrt{sf'(s)y_D}} \right] \frac{1}{e^{\sqrt{sf'(s)y_D}} - e^{-\sqrt{sf'(s)y_D}}} \]  
.................................(B-21)

Where \( y_{Dw} = \frac{Y_c}{\sqrt{A_{cw}}} \)

\[ P_{DL} = \frac{2\pi}{s\sqrt{sf'(s)}} \left[ \frac{e^{\sqrt{sf'(s)y_D}} + \frac{1}{e^{\sqrt{sf'(s)y_D}}}} {e^{\sqrt{sf'(s)y_D}} - \frac{1}{e^{\sqrt{sf'(s)y_D}}}} \right] \]
\[ p_{wDL} = \frac{2\pi}{s\sqrt{f(s)}} \left[ \frac{e^{2\sqrt{f(s)y_0}} + 1}{e^{2\sqrt{f(s)y_0}} - 1} \right] \]  \hspace{1cm} \text{..................................(B-22)}

dividing by \( e^{2\sqrt{f(s)y_0}} \)

\[ p_{wDL} = \frac{2\pi}{s\sqrt{f(s)}} \left[ \frac{1 + e^{-2\sqrt{f(s)y_0}}}{1 - e^{-2\sqrt{f(s)y_0}}} \right] \]  \hspace{1cm} \text{..................................(B-23)}

In Laplace space, the constant pressure case at the wellbore can be found from the solution for the constant rate case given by Eq. B-23 using Eq. B-24.

\[ q_{DL} = \frac{1}{s}, p_{wDL} \]  \hspace{1cm} \text{..................................(B-24)}

Eq. B-23 thus becomes for the constant pressure case

\[ \frac{1}{q_{DL}} = \frac{2\pi}{\sqrt{f(s)}} \left[ \frac{1 + e^{-2\sqrt{f(s)y_0}}}{1 - e^{-2\sqrt{f(s)y_0}}} \right] \]  \hspace{1cm} \text{..................................(B-25)}

Eq. B-25 can then be inverted to obtain the solutions as a function of time using suitable Laplace numerical inversion algorithms such as Stehfest’s inversion algorithm.
APPENDIX C

DEVELOPMENT OF ANALYSIS EQUATIONS

In this section, the analysis equations for the linear model are derived.

C-1 Region 1

This region represents early linear flow in the fracture system only. The Laplace space solution for the constant pressure inner boundary, closed outer boundary reservoir (slab matrix) is given from Eq. B-25 by

\[
\frac{1}{q_{DL}} = \frac{2\pi}{sf(s)} \left[ \frac{1 + e^{-2\sqrt{sf(s)y_{De}}}}{1 - e^{-2\sqrt{sf(s)y_{De}}}} \right] \quad \text{where} \quad y_{De} = \frac{y}{\sqrt{A_w}}
\]

This can be shown to be the same as

\[
\frac{1}{q_{DL}} = \frac{2\pi}{sf(s)} \coth \left( \sqrt{sf(s)y_{De}} \right)
\]

using \( \coth(x) = \frac{e^{x} + 1}{e^{x} - 1} \) ..................................(C-1)

Approximately for \( x > 3, \ \coth(x) = 1 \)

Therefore \( \coth \left( \sqrt{sf(s)y_{De}} \right) = 1 \) when \( \sqrt{sf(s)y_{De}} > 3 \) ..............................(C-3)

Eq. C-1 becomes

\[
\frac{1}{q_{DL}} = \frac{2\pi}{sf(s)}
\]

.................................(C-4)

For slab matrix, \( f(s) = \omega + \sqrt{\frac{\lambda_{Ac}}{3s}} (1 - \omega) \tanh \left( \frac{3(1 - \omega)s}{\lambda_{Ac}} \right) \) .................................(C-5)

Assume \( \omega >>>>> \sqrt{\frac{\lambda_{Ac}}{3s}} (1 - \omega) \tanh \left( \frac{3(1 - \omega)s}{\lambda_{Ac}} \right) \) .................................(C-6)

Therefore \( f(s) = \omega \) .................................(C-7)
Eq. C-4 becomes
\[
\frac{1}{q_{DL}} = \frac{2\pi}{\sqrt{s}} \frac{1}{\sqrt{\omega}}
\] ..........................(C-8)

or \[
q_{DL} = \frac{1}{2\pi \sqrt{s}} \sqrt{\omega}
\] ..........................(C-9)

Inverting from Laplace space

\[
q_{DL} = \frac{1}{2\pi \sqrt{\pi D_{Ac} / \omega}}
\] ..........................(C-10)

\[
q_{DL} = \frac{1}{2\pi \sqrt{\pi D_{Ac} / \omega}}
\] ..........................(C-11)

From the assumptions in Eqs. C-3 and C-6 we can derive approximate equations for the approximate range where Eq. C-11 is valid

From Eq. C-3, \[\sqrt{sf(s)y_{De}} > 3\]

Applying Eq. C-7

Thus \[\sqrt{s\omega y_{De}} > 3\] ..........................(C-12)

And \[s > \frac{9}{y_{De} \omega}\]

Multiplying by \(\frac{1}{s^2}\)

\[\frac{1}{s} > \frac{1}{s^2} \frac{9}{y_{De} \omega}\] ..........................(C-13)

Inverting from Laplace space

\[1 > \frac{9}{y_{De} \omega}\] ..........................(C-14)
And \( t_{DAc} < \frac{y_{De}^2 \omega}{9} \) \hspace{1cm} \text{........................................}(C-15)

From Eq. C-6, \( \omega >>>> \sqrt{\frac{\lambda_{Ac}}{3s}} (1-\omega) \tanh \left( \sqrt{\frac{3(1-\omega)s}{\lambda_{Ac}}} \right) \) implies that

\[
\sqrt{\frac{\lambda_{Ac}}{3s}} (1-\omega) \tanh \left( \sqrt{\frac{3(1-\omega)s}{\lambda_{Ac}}} \right) = 0
\]

\hspace{1cm} \text{........................................}(C-16)

This implies that \( s \) is large (very small times, \( t_{DAc} \))

We can thus give an approximate range for Region 1 as

\[
0 < t_{DAc} < \frac{y_{De}^2 \omega}{9}
\]

\hspace{1cm} \text{........................................}(C-17)

**C-2 Region 2**

This represents bilinear flow caused by simultaneous depletion in the fracture system and matrix. The Laplace space solution for the constant pressure inner boundary, closed outer boundary reservoir (slab matrix) is given from Eq. B-25 by

\[
\frac{1}{q_{DL}} = \frac{2\pi s}{\sqrt{sf(s)}} \left[ \frac{1 + e^{-\sqrt{f(s)}_{De}}}{1 - e^{-\sqrt{f(s)}_{De}}} \right] \text{ where } y_{De} = \frac{y_r}{\sqrt{A_{rw}}}
\]

From Eq. C-1,

\[
\frac{1}{q_{DL}} = \frac{2\pi s}{\sqrt{sf(s)}} \coth \left( \sqrt{sf(s)} y_{De} \right)
\]

\hspace{1cm} \text{........................................}(C-18)

For slab matrix,

\[
f(s) = \omega + \sqrt{\frac{\lambda_{Ac}}{3s}} (1-\omega) \tanh \left( \sqrt{\frac{3(1-\omega)s}{\lambda_{Ac}}} \right)
\]

\hspace{1cm} \text{........................................}(C-19)

Assume \( \omega <<<< \sqrt{\frac{\lambda_{Ac}}{3s}} (1-\omega) \tanh \left( \sqrt{\frac{3(1-\omega)s}{\lambda_{Ac}}} \right) \)

\hspace{1cm} \text{........................................}(C-20)

and \( 1 - \omega \approx 1 \)
Approximately for $x > 3$, $\tanh(x) \approx 1$

Assume $\tanh\left(\frac{3(1-\omega)s}{\lambda}\right) \approx 1$ ...........................................(C-21)

Thus $\frac{3s}{\lambda_{Ac}} > 3$ ...........................................(C-22)

Therefore Eq. C-19 becomes

$$f(s) = \sqrt{\frac{\lambda_{Ac}}{3s}}$$ ...........................................(C-23)

Approximately For $x > 3$ $\coth(x) \approx 1$

Therefore In Eq. C-18

$$\coth\left(\frac{sf(s)}{y_{Dc}}\right) = 1 \text{ when } \sqrt{sf(s)}y_{Dc} > 3$$ ...........................................(C-24)

And Eq. C-18 becomes

$$\frac{1}{q_{DL}} = \frac{2\pi s}{\sqrt{sf(s)}}$$ ...........................................(C-25)

Substituting Eq. C-23 in C-25

$$\frac{1}{q_{DL}} = 2\pi \left(\frac{s^{0.25}}{s^{0.25} + \lambda_{Ac}^{0.25}}\right) = \frac{2\pi}{\lambda_{Ac}^{0.25}} s^{0.75}$$

and

$$q_{DL} = \frac{\lambda_{Ac}^{0.25}}{(2\pi)\left(s^{0.25}\right)s^{0.75}}$$ ...........................................(C-26)

Inverting from Laplace space

$$q_{DL} = \frac{\lambda_{Ac}^{0.25}}{(2\pi)\left(s^{0.25}\right)\Gamma(0.75)} \Gamma(\omega)$$ where $\Gamma(\omega)$ is the gamma function.
From the assumptions in Eqs. C-22 and C-24 we can derive approximate equations for the approximate range where Eq. C-26 is valid.

From Eq. C-22, \[ \sqrt{\frac{3s}{\lambda_{Ac}}} > 3 \]

And \[ \frac{3s}{\lambda_{Ac}} > 9 \] \hspace{1cm} \text{(C-28)}

Multiplying by \( \frac{1}{s^2} \)

\[ \frac{1}{s} \frac{3}{\lambda_{Ac}} > \frac{1}{s^2} 9 \] \hspace{1cm} \text{(C-29)}

Inverting from Laplace space

\[ \frac{3}{\lambda_{Ac}} > t_{DAc} 9 \] \hspace{1cm} \text{(C-30)}

And \[ t_{DAc} < \frac{1}{3\lambda_{Ac}} \] \hspace{1cm} \text{(C-31)}

From Eq. C-24, \[ \sqrt{f(s)y_{De}} > 3 \] \hspace{1cm} \text{(C-32)}

Applying Eq. C-23 to Eq. C-32

\[ \frac{s^{0.25} \lambda_{Ac}^{0.25}}{3^{0.25}} y_{De} > 3 \] \hspace{1cm} \text{(C-33)}

And \[ s > \left( \frac{3}{y_{De}} \right)^4 \frac{3}{\lambda_{Ac}} \] \hspace{1cm} \text{(C-34)}
Multiplying by \( \frac{1}{s^2} \)

\[
\frac{1}{s} > \frac{1}{s^2} \left( \frac{3}{y_{De}} \right)^4 \frac{3}{\lambda_{Ac}}
\]

..............................(C-35)

Inverting from Laplace space

\[
1 > t_{DaC} \left( \frac{3}{y_{De}} \right)^4 \frac{3}{\lambda_{Ac}}
\]

..............................(C-36)

And \( t_{DaC} < \left( \frac{y_{De}}{3} \right)^4 \frac{\lambda_{Ac}}{3} \)

It thus appears that an approximate criteria for Region 2 is

\[
t_{DaC} < \frac{1}{3\lambda_{Ac}}
\]

and \( t_{DaC} < \left( \frac{y_{De}}{3} \right)^4 \frac{\lambda_{Ac}}{3} \)

..............................(C-37)

**C-3 Region 3**

This region represents the homogeneous reservoir case. The Laplace space solution for the constant pressure inner boundary, closed outer boundary reservoir (slab matrix) is given from Eq. B-25 by

\[
\frac{1}{q_{DL}} = \frac{2\pi}{\sqrt{yf(s)}} \left[ \frac{1 + e^{-2\sqrt{yf(s)}y_{De}}}{1 - e^{-2\sqrt{yf(s)}y_{De}}} \right] \quad \text{where} \quad y_{De} = y_{c}/\sqrt{A_{cw}}
\]

From Eq. C-1,

\[
\frac{1}{q_{DL}} = \frac{2\pi}{\sqrt{yf(s)}} \coth(\sqrt{yf(s)}y_{De})
\]

..............................(C-38)

Approximately for \( x > 3 \), \( \coth(x) = 1 \)

Therefore \( \coth(\sqrt{yf(s)}y_{De}) = 1 \) when \( \sqrt{yf(s)}y_{De} > 3 \) ..............................(C-39)
Eq. (C-38) becomes\[ \frac{1}{q_{DL}} = \frac{2\pi n}{\sqrt{sf(s)}} \]……………………………(C-40)

For the homogeneous case, \( f(s) = 1 \) ………………………………(C-41)

and\[ \frac{1}{q_{DLh}} = \frac{2\pi n}{\sqrt{sf(s)}} \]……………………………(C-42)

Eq. C-40 becomes\[ \frac{1}{q_{DLh}} = \frac{2\pi n}{\sqrt{s}} \]……………………………(C-43)

or \[ q_{DLh} = \frac{1}{2\pi \sqrt{s}} \]……………………………(C-44)

Inverting from Laplace space\[ q_{DLh} = \frac{1}{2\pi \sqrt{n_0}} \]……………………………(C-44)

Where \[ \frac{1}{q_{D_i}} = \frac{k\sqrt{A_0}}{1422q_i T} \left[ \frac{m(p_i) - m(p_{ref})}{\phi \mu_c A_{ref}} \right] \] ; \[ t_{D_i} = \frac{0.00633kT}{(\phi \mu_c)A_{ref}} \] and \( k \) is the homogeneous reservoir permeability.

From the assumptions in Eqs. C-39 and C-41 we can derive approximate equations for the approximate range where Eq. C-44 is valid

From Eq. C-39, \( \sqrt{sf(s)y_{De}} > 3 \)

Applying Eq. C-41

Thus \[ \sqrt{sy_{De}} > 3 \]……………………………(C-45)

And \[ s > \frac{9}{y_{De}^2} \]……………………………(C-46)
Multiplying by $\frac{1}{s^2}$

\[
\frac{1}{s} > \frac{1}{s^2} \frac{9}{y_{De}} \tag{C-47}
\]

Inverting from Laplace space

\[
1 > t_{DAc} \frac{9}{y_{De}^2} \tag{C-48}
\]

And \( t_{DAc} < \frac{y_{De}^2}{9} \tag{C-49} \)

We can thus give an approximate criteria for Region 3 as

\[
t_{DAc} < \frac{y_{De}^2}{9} \tag{C-50}
\]

**C-4 Region 4**

This represents the transient linear case when the transient response is primarily from drainage of the matrix. The Laplace space solution for the constant pressure inner boundary, closed outer boundary reservoir (slab matrix) is given from Eq. B-25 by

\[
\frac{1}{q_{DL}} = \frac{2\pi}{\sqrt{sf(s)}} \left[ 1 + e^{-2\sqrt{sf(s)}y_{De}} \right] \left[ 1 - e^{-2\sqrt{sf(s)}y_{De}} \right] \tag{C-51}
\]

where \( y_{De} = \frac{y_c}{\sqrt{\lambda_{cw}}} \)

From Eq. C-1,

\[
\frac{1}{q_{DL}} = \frac{2\pi}{\sqrt{sf(s)}} \coth(\sqrt{sf(s)} y_{De}) \tag{C-52}
\]

For slab matrix,

\[
f(s) = \omega + \frac{\lambda_{Ac}}{3s} (1 - \omega) \tanh \left( \frac{3(1 - \omega)s}{\lambda_{Ac}} \right) \tag{C-53}
\]

Assume \( \omega << \frac{\lambda_{Ac}}{3s} (1 - \omega) \tanh \left( \frac{3(1 - \omega)s}{\lambda_{Ac}} \right) \tag{C-54} \)
and \( 1 - \omega \approx 1 \)

Approximately for \( x > 3 \), \( \tanh(x) \approx 1 \)

Assume \( \tanh\left( \frac{3(1 - \omega)s}{\lambda_{Ac}} \right) = 1 \)  

\[ \text{Thus } \sqrt{\frac{3s}{\lambda_{Ac}}} > 3 \]

Therefore, Eq. C-52 becomes

\[ f(s) = \sqrt{\frac{\lambda_{Ac}}{3s}} \]

Taylor’s series expansion of

\[ \coth(x) = \frac{1}{x} + \frac{x}{3} - \frac{x^3}{45} + \frac{2x^5}{945} + \ldots \]

Taking first term of series \( \coth(x) = \frac{1}{x} \)

Thus, In Eq. C-51, assuming \( \coth(\sqrt{s}f(s)y_{De}) = \frac{1}{\sqrt{s}f(s)y_{De}} \)

Eq. C-51 becomes \( \frac{1}{q_{DL}} = \frac{2\pi}{\sqrt{s}f(s)y_{De}} \frac{1}{\sqrt{s}f(s)y_{De}} \)

and \( \frac{1}{q_{DL}} = \frac{2\pi}{f(s)y_{De}} \frac{1}{\sqrt{s}f(s)y_{De}} \)

Substituting Eq. C-56 in C-60

\[ \frac{1}{q_{DL}} = 2\pi \sqrt{\frac{3s}{\lambda_{Ac}}} \frac{1}{y_{De}} = 2\pi \sqrt{\frac{3}{\lambda_{Ac}}} \frac{1}{y_{De}} \]

and \( q_{DL} = \frac{1}{2\pi \sqrt{3}} \sqrt{\frac{\lambda_{Ac}}{y_{De}}} \)
Inverting from Laplace space

\[ q_{DL} = \frac{1}{2\pi \sqrt{\lambda_{Ac}}} \sqrt{\frac{\lambda_{Ac}}{3}} y_{De} \] ........................................(C-61)

From the assumptions in Eqs. C-55 and C-59 we can derive approximate equations for the approximate range where Eq. C-61 is valid

From Eq. C-55, \( \sqrt{\frac{3s}{\lambda_{Ac}}} > 3 \)

And \( \frac{3s}{\lambda_{Ac}} > 9 \) ........................................(C-62)

Multiplying by \( \frac{1}{s^2} \)

\[ \frac{1}{s} \frac{3}{\lambda_{Ac}} > \frac{1}{s^2} 9 \] ........................................(C-63)

Inverting from Laplace space

\[ \frac{3}{\lambda_{Ac}} > t_{DAc} 9 \] ........................................(C-64)

And \( t_{DAc} < \frac{1}{3\lambda_{Ac}} \) ........................................(C-65)

From Eq. C-59, \( Coth(\sqrt{sf(s)} y_{De}) = \frac{1}{\sqrt{sf(s)} y_{De}} \)

Since \( Coth(x) = \frac{1}{x} \) when approximately \( x < 0.5 \)  ........................................(C-66)

This implies that \( \sqrt{sf(s)} y_{De} < 0.5 \)  ........................................(C-67)

Applying Eq. C-56

\[ \left( \frac{\lambda_{Ac} s}{3} \right)^{0.25} y_{De} < 0.5 \] ........................................(C-68)

And

\[ s < \frac{3}{\lambda_{Ac}} \left( \frac{0.5}{y_{De}} \right)^4 \] ........................................(C-69)
Multiplying by $\frac{1}{s^2}$

$$\frac{1}{s} < \frac{1}{s^2} \frac{3}{\lambda_{Ac}} \left( \frac{0.5}{y_{De}} \right)^4$$

..............................(C-70)

Inverting from Laplace space

$$1 < t_{DAc} \frac{3}{\lambda_{Ac}} \left( \frac{0.5}{y_{De}} \right)^4$$

..............................(C-71)

$$t_{DAc} > \frac{\lambda_{Ac}}{3} \left( \frac{y_{De}}{0.5} \right)^4$$

..............................(C-72)

We can thus give an approximate range from Eq. C-65 and C-72 for Region 4 as

$$\frac{\lambda_{Ac}}{3} \left( \frac{y_{De}}{0.5} \right)^4 < t_{DAc} < \frac{1}{3\lambda_{Ac}}$$

..............................(C-73)
APPENDIX D
HOMOGENEOUS LINEAR RESERVOIR RESPONSE

In this section, the derivations of the equations for the homogeneous, constant pressure inner boundary, bounded rectangular reservoir are shown. This equation is derived beginning with Eq. B-25 for the linear model.

\[
\frac{1}{q_{DL}} = \frac{2\pi}{\sqrt{sf}(s)} \left[ \frac{1+e^{-2\sqrt{sf(y)_{in}}}}{1-e^{-2\sqrt{sf(y)_{in}}}} \right]
\]

As shown in Appendix C, this is the same as

\[
\frac{1}{q_{DL}} = \frac{2\pi}{\sqrt{sf}(s)} \text{Coth} \left( \sqrt{sf(y)_{De}} \right)
\]

For the homogeneous case, \( f(s) = 1 \), and

\[
\frac{1}{q_{DLh}} = \frac{2\pi}{\sqrt{sf}(s)} \text{Coth} \left( \sqrt{sf(y)_{De}} \right)
\]

thus

\[
\frac{1}{q_{DLh}} = \frac{2\pi}{\sqrt{s}} \text{Coth} \left( \sqrt{s_{y_{De}}} \right) \tag{D-1}
\]

Or

\[
q_{DLh} = \frac{\sqrt{s}}{2\pi} \text{Tanh} \left( \sqrt{s_{y_{De}}} \right) \tag{D-2}
\]

\[
\text{Tanh}(x) = 1 + 2 \sum_{n=1}^{\infty} (-1)^n e^{-2nx} \tag{D-3}
\]
Applying Eq. D-3 to D-2

\[
q_{DLh} = \frac{\sqrt{s}}{2\pi s} \left[ 1 - 2e^{-2\sqrt{s}r_{yw}} + 2e^{-4\sqrt{s}r_{yw}} - 2e^{-6\sqrt{s}r_{yw}} + \ldots \right]
\]

………………………. (D-4)

\[
q_{DLh} = \frac{1}{2\pi \sqrt{s}} \left[ 1 - 2e^{-2\sqrt{s}r_{yw}} + 2e^{-4\sqrt{s}r_{yw}} - 2e^{-6\sqrt{s}r_{yw}} + \ldots \right]
\]

………………………. (D-5)

Inverting from Laplace space

\[
q_{DLh} = \frac{1}{2\pi \sqrt{\pi DLh}} \left[ 1 - 2e^{\left(\frac{y_{lw}}{\sqrt{DLh}}\right)} + 2e^{\left(\frac{y_{lw}}{\sqrt{DLh}}\right)} - 2e^{\left(\frac{y_{lw}}{\sqrt{DLh}}\right)} + \ldots \right]
\]

………………………. (D-6)

\[
q_{DLh} = \frac{1}{2\pi \sqrt{\pi DLh}} \left[ 1 + 2\sum_{n=1}^{\infty} (-1)^n e^{\left(\frac{n^2 y_{lw}}{\sqrt{DLh}}\right)} \right]
\]

………………………. (D-7)

Eq. D-7 is the exact analytical solution for Eq. B-25 for the homogeneous case.
APPENDIX E

EFFECT OF SKIN

Skin is normally defined as a dimensionless pressure for the slightly compressible fluid case given by

\[ s_{rw} = \frac{kh\Delta p_s}{141.2qB\mu} \]  

(E-1)

Where the skin is an additional dimensionless pressure

\[ p_{wD} = p_D + s_{rw} \]  

(E-2)

There have been different definitions for the dimensionless pressure used in pressure transient horizontal wells. One set of investigators\(^{42,48,54,55}\) define

\[ p_{Dw} = \frac{kh\Delta p}{141.2qB\mu} \]  

(E-3)

While Kuchuk\(^{50}\) and Lichtenberger\(^{60}\) define

\[ p_{DH} = \frac{kL_w\Delta p}{141.2qB\mu} \]  

and thus

\[ s_H = \frac{kL_w\Delta p_s}{141.2qB\mu} \]  

(E-4)

For the linear model we will define

\[ 2\pi s_{Ac} = \frac{k\sqrt{A_{rw}\Delta p_s}}{141.2qB\mu} \]  

which represents the skin defined in El-Banbi\(^{16}\).

In this section, an investigation will be conducted using different software to determine how their skin is defined or represented. The test model is the constant rate, horizontal well, homogeneous rectangular bounded reservoir case. The software to be
used in this exercise are *Kappa Ecrin v4.02.02 (Saphir module)*, *Fekete (WellTest32 Module version 7.0.0.2)* and the numerical simulator *ECLIPSE version 2007.1*. The results will be compared with our linear model given in Appendix B (homogeneous case, \( f(s) = 1 \)). The dataset is given in Table E-1. Two cases will be presented. Case 1 is one in which skin = zero and Case 2 is one in which skin = 10. Skin = 0 and Skin = 10 means that 0 and 10 will be input into each software for the required case.

The results from Case 1 are shown in Figs. E-1 and E-2. Fig. E-1 shows the results plotted in terms of normal variables, log-log plot of \( [p_i - p_{wf}] / q \) against time. It can
be observed from Fig. E-1 that the results from the three software show similar results except for Saphir which deviates at later times. Our linear model differs as expected from the three software by the convergence skin expected with an actual horizontal well.

Fig. E-1 – Case 1 (skin = 0) - Comparison of Results. The three software show similar results except for Saphir which deviates at later times. Our linear model differs as expected from the three software by the convergence skin expected with an actual horizontal well.
The generated pressure and time results for *Fekete, ECLIPSE* from Fig. E-1 are converted to $p_{Drw}$ using Eq. E-3 and $t_{Drw}$ using Eq. E-5 and are plotted in Fig. E-2. Fig. E-2 shows the results plotted as a dimensionless plot of pressure, $p_{Drw}$ against dimensionless time, $t_{Drw}$. The derivative is also added to the plot.

$$t_{Drw} = \frac{0.00633kt}{\phi\mu c r_w^2}$$

(E-5)

The results from the linear model are converted to the above variables $p_{Drw}$ and $t_{Drw}$ using the relations

$$p_{Drw} = p_{DL} \left( \frac{h}{\sqrt{A_{cw}}} \right) \text{ and } t_{Drw} = t_{DL} \left( \frac{r_w^2}{A_{cw}} \right)$$

(E-6)

Fig. E-2 shows the same results as Fig. E-1. The three software show similar results except for Saphir which deviates at later times (Saphir’s horizontal well model
might be different from the others). Our linear model as expected indicates linear flow (half-slope on derivative). Our linear model also differs as expected from the three software by the convergence skin expected with an actual horizontal well. The effect of convergence skin has been discussed in Chapter III.

The results from Case 2 (skin = 10) are shown in Figs. E-3 and E-4. Fig. E-3 shows the results plotted in terms of normal variables as a log-log plot of \( \frac{p_i - p_{wf}}{q} \) against time. It can be observed from Fig. E-3 that the results from ECLIPSE and Fekete are similar. The results from Saphir differ from the others indicating that the skin definition is different. The linear model obviously also differs from the other results due to its different skin definition. Fig. E-4 shows the corresponding dimensionless pressure and time plot similar to Fig. E-3 except that the skin=10 runs are also added to the plot. The results are summarized in Table E-2.

![Comparison of Results](image)

**Fig. E-3 – Case 2 (skin = 10) - Comparison of Results.** ECLIPSE and Fekete are similar while Saphir and the Linear model are different because of the different skin definitions.
Fig. E-4 – Comparison of Results (skin = 0 and skin =10) Dimensionless Pressure against Dimensionless Time. Fekete and ECLIPSE have similar definitions of skin different from the other software.

It can be observed from Table E-2 that the Fekete definition is based on $L_w$ as shown in Eq. E-4. The conversion to conventional definitions results in

$$s_m = 10 \frac{h}{L_w} = 10 \frac{30}{2,000} = 0.15$$

The Saphir definition is obviously based on $h$. The linear model definition as was previously shown is based on $\sqrt{A_{cw}}$.

$$2\pi \frac{h}{\sqrt{A_{cw}}} = (2\pi)(10) \frac{h}{\sqrt{A_{cw}} = (2\pi)(10) \frac{30}{\sqrt{120,000}} = 5.44$$

Table E-2 – Summary of Results from Fig. E-4.
When utilizing the different software these different skin definitions should be noted so as to ensure that accurate interpretation and calculations.

The results from Fekete are plotted on a \( \frac{m(p_i) - m(p_{wf})}{q} \) against \( t^{0.5} \) plot in Fig. E-5. It can be observed from Fig E-5 that there are two parallel lines representing the response in the transient linear region for the skin = 0 and skin = 10 cases. It can thus be concluded that the effect of skin is a constant offset on this plot.

![Fig. E-5 – Comparison of Results (skin=0 and skin=10) - Specialized Plot of \( \frac{m(p_i) - m(p_{wf})}{q} \) against \( t^{0.5} \). The two plots are parallel with a constant offset showing the effect of skin. The initial curve is due to the horizontal well radial flow present in the Fekete model.](image-url)
An equation\textsuperscript{60} for computing the convergence skin in the linear flow period which account for additional pressure drop caused by linear flow streamlines converging to an actual horizontal well is given by

\[
s_c = \ln \left[ \frac{\pi p_{wf}}{h} \left( 1 + \frac{k_v}{k_H} \sqrt{\frac{H}{L}} \sin \left( \frac{\pi d}{h} \right) \right) \right] \tag{E-7}
\]

This equation should be added to the response from our linear model to obtain similar results as in Fekete and ECLIPSE as demonstrated in Chapter III.

**E.1 Constant \( p_{wf} \) Case**

In this section, an investigation will be conducted using the constant \( p_{wf} \), horizontal well, homogeneous rectangular bounded reservoir case. Only ECLIPSE and the linear model will be used for this test. The data set is the same as given in Table E-1 except that a well flowing pressure of 250 psi is used. The results for ECLIPSE are shown in Figs. E-6 and E-7. The results for the linear model is shown in Fig. E-8 and E-9. It can be observed from Figs. E-6 and E-8 that the effect of the skin is to lower the rates in the transient linear region. This is contrary to observations with the constant rate case. It can be observed from Figs. E-7 and E-9 that the effect of the skin decreases with increasing time. This is contrary to the parallel lines observed in Fig. E-5 for the constant rate case.
Fig. E-6 – Comparison of Results for ECLIPSE (skin = 0 and 10, Constant Pressure case) – Log-log Plot of Rate against Time. The skin = 10 case shows lower rates.

Fig. E-7 – Comparison of Results for ECLIPSE (skin = 0 and 10, Constant Pressure case) – Specialized Plot of \([p_i-p_{wf}]/q_g\) against \(t^{0.5}\). There is a diminishing effect of skin with time.
Fig. E-8 – Comparison of Results for the Linear Model (skin =0 and 10, Constant \( p_{wf} \) case) – Log-log Plot of Rate against Time. The skin = 10 case shows lower rates.

Fig. E-9 – Comparison of Results for the Linear Model (skin =0 and 10, Constant \( p_{wf} \) case) – Specialized Plot of \( \frac{[p_i-p_{wf}]/q}{g} \) against \( t^{0.5} \). There is a diminishing effect of skin with time.
APPENDIX F

DERIVATION OF THE EQUATION FOR THE CONSTANT BOTTOMHOLE PRESSURE EFFECT OF SKIN

(HOMOGENEOUS, LINEAR RESERVOIR)

In this section, the constant pressure effect of skin shown previously in Appendix D will be derived for the infinite, homogeneous linear reservoir case.

The equation\(^{16}\) for the linear model (infinite reservoir case) is given by

\[
\frac{1}{q_{DL}} = \frac{2\pi}{\sqrt{sf(s)}} \left[ 1 + s_{Ac} \sqrt{sf(s)} \right] \quad \text{.........................................(F-1)}
\]

For the homogeneous reservoir case, \(f(s) = 1\)

Thus

\[
\frac{1}{q_{DLh}} = \frac{2\pi}{\sqrt{s}} \left[ 1 + s_{Ach} \sqrt{s} \right] \quad \text{.........................................(F-2)}
\]

\[
q_{DLh} = \frac{1}{\frac{2\pi}{\sqrt{s}} \left[ 1 + s_{Ach} \sqrt{s} \right]} \quad \text{.........................................(F-3)}
\]

and solving by partial fractions

\[
\frac{1}{2\pi \sqrt{s} \left[ 1 + s_{Ach} \sqrt{s} \right]} = \frac{A}{2\pi \sqrt{s} \left[ 1 + s_{Ach} \sqrt{s} \right]} + \frac{B}{1 + s_{Ach} \sqrt{s}} \quad \text{.........................................(F-4)}
\]

\[
1 = A \left( 1 + s_{Ach} \sqrt{s} \right) + B 2\pi \sqrt{s} \quad \text{.........................................(F-5)}
\]

put \(\sqrt{s} = 0\) into Eq. F-4 and thus \(A = 1\)
put \( \sqrt{s} = -\frac{1}{S_{Ah}} \) into Eq. F-4 and thus \( B = \frac{S_{Ah}}{2\pi} \)

and thus Eq. F-3 can be expressed as

\[
q_{DL_h} = \frac{1}{2\pi \sqrt{s}} + \frac{-S_{Ah}/2\pi}{1 + S_{Ah} \sqrt{s}}
\]

………………………………..(F-6)

\[
q_{DL_h} = \ell^{-1} \left[ \frac{1}{2\pi \sqrt{s}} \right] + \ell^{-1} \left[ \frac{-S_{Ah}/2\pi}{1 + S_{Ah} \sqrt{s}} \right]
\]

………………………………..(F-7)

\[
q_{DL_h} = \ell^{-1} \left[ \frac{1}{2\pi \sqrt{s}} \right] + \ell^{-1} \left[ \frac{1}{1/\sqrt{s}_{Ah} + \sqrt{s}} \right]
\]

………………………………..(F-8)

\[
q_{DL_h} = \frac{1}{2\pi \sqrt{\pi} D_{MCh}} - \frac{1}{2\pi} \left[ \frac{1}{\sqrt{\pi} D_{MCh}} - \frac{1}{S_{Ah}} e^{(\sqrt{2} \sqrt{s}_{Ah} \ t_{DAh})} \text{erfc} \left( \frac{1}{S_{Ah}} \sqrt{t_{DAh}} \right) \right]
\]

………………………………..(F-9)

\[
q_{DL_h} = \frac{1}{2\pi S_{Ah}} e^{(\sqrt{2} \sqrt{s}_{Ah} \ t_{DAh})} \text{erfc} \left( \frac{1}{S_{Ah}} \sqrt{t_{DAh}} \right)
\]

………………………………..(F-10)

Eq. F-10 gives the transient response for an infinite homogeneous, constant pressure inner boundary reservoir with a skin effect, \( s_{Ah} \) present.

It can be observed from Eq. F-10 that at small times, \( t_{DAc} = 0 \)

\[
q_{DL_h} = \frac{1}{2\pi S_{Ah}}
\]

………………………………..(F-11)

And at large times \( t_{DAc} = \infty \)

Using first term of asymptotic expansion for \( \text{erfc}(x) \) for large \( x \)

\[
\text{erfc}(x) = \frac{e^{-x^2}}{x \sqrt{\pi}}
\]

Eq. F-10 becomes
\[ q_{DLh} = \frac{1}{2\pi n_{Ach}} e^{\frac{1}{\sigma_{Ach}^2} t_{DLh}} e^{\frac{1}{S_{Ach}^2 \sqrt{T_{DLh}}} \sqrt{\pi}} \] ..........................(F-12)

\[ q_{DLh} = \frac{1}{2\pi \sqrt{\pi}_{DLh}} \] ..........................(F-13)
APPENDIX G
DERIVATION OF THE EQUATION FOR THE SQUARE ROOT OF
TIME LINEAR DERIVATIVE (HOMOGENEOUS, LINEAR
RESERVOIR, CONSTANT BOTTOMHOLE PRESSURE)

In this section, the analytical equation for linear derivative for the linear homogeneous
reservoir (constant pressure inner boundary, infinite) with a skin effect will be derived.

From Eq. F-10,
\[
q_{DLh} = \frac{1}{2\pi s_{Ach}} e^{\sqrt{s_{Ach}} t_{DLh}} \text{erfc} \left( \frac{1}{s_{Ach}} \sqrt{t_{DLh}} \right)
\]  
……………………………..(G-1)

We know that
\[
\frac{d\left( \frac{1}{q_{DLh}} \right)}{dt_{DLh}} = -\frac{1}{q_{DLh}^2} \frac{dq_{DLh}}{dt_{DLh}}
\]
and
\[
\frac{d\left( \frac{1}{q_{DLh}} \right)}{d\sqrt{t_{DLh}}} = 2\sqrt{t_{DLh}} \left( -\frac{1}{q_{DLh}^2} \right) \frac{dq_{DLh}}{dt_{DLh}}
\]  
……………………………..(G-2)

Let \( u = \frac{1}{s_{Ach}} \sqrt{t_{DLh}} \) and thus \( u^2 = \frac{1}{s_{Ach}^2} t_{DLh} \)

Thus Eq. G-1 becomes
\[
q_{DLh} = \frac{1}{2\pi s_{Ach}} e^{u^2} \text{erfc}(u)
\]  
……………………………..(G-3)
Differentiating

\[ \frac{dq_{DLh}}{dt_{Dach}} = \frac{1}{2\pi_s^{Ach}} e^{u^2} \left( \frac{d}{dt_{Dach}} [\text{erfc}(u)] + \frac{d}{dt_{Dach}} \left[ \frac{1}{2\pi_s^{Ach}} e^{u^2} \right] \right) \]  
\[ \text{...............(G-4)} \]

We know that \( \frac{d}{dx} \text{erfc}(x) = -\frac{2}{\sqrt{\pi}} e^{-x^2} \)

Thus

\[ \frac{d}{du} \text{erfc}(u) = -\frac{2}{\sqrt{\pi}} e^{-u^2} \]

And

\[ \frac{d}{dt_{Dach}} = \frac{d}{du} \frac{du}{dt_{Dach}} \]

Thus

\[ \frac{d}{dt_{Dach}} [\text{erfc}(u)] = \frac{d}{du} \frac{du}{dt_{Dach}} [\text{erfc}(u)] = -\frac{2e^{-u^2}}{\sqrt{\pi}} \frac{1}{s_{Ach}} \frac{1}{\sqrt{t_{Dach}}} \]

Eq. G-4 becomes

\[ \frac{dq_{DLh}}{dt_{Dach}} = \frac{1}{2\pi_s^{Ach}} e^{u^2} \left( -\frac{2e^{-u^2}}{\sqrt{\pi}} \frac{1}{s_{Ach}} \frac{1}{\sqrt{t_{Dach}}} + \text{erfc}(u) \left( \frac{1}{2\pi_s^{Ach}} e^{u^2} \right) \right) \]
\[ \text{...............(G-5)} \]

Applying Eq. G-2 to obtain the square root of time derivative

\[ \frac{d}{dt_{Dach}} \left( \frac{1}{\sqrt{q_{DLh}}} \right) = 2\sqrt{t_{Dach}} \left( -\frac{1}{q_{DLh}^2} \right) \left( \frac{1}{2\pi_s^{Ach}} e^{u^2} \right) \left( -\frac{2e^{-u^2}}{\sqrt{\pi}} \frac{1}{s_{Ach}} \frac{1}{\sqrt{t_{Dach}}} + \text{erfc}(u) \left( \frac{1}{2\pi_s^{Ach}} e^{u^2} \right) \right) \]
\[ \text{...............(G-6)} \]

\[ \frac{d}{dt_{Dach}} \left( \frac{1}{\sqrt{q_{DLh}}} \right) = \frac{1}{q_{DLh}^2 s_{Ach}^2 \pi^{1.5}} - \sqrt{t_{Dach}} \frac{1}{q_{DLh}^2 s_{Ach}^2 \pi^3} e^{\left( \frac{1}{2s_{Ach}^2} \sqrt{t_{Dach}} \right)} \text{erfc} \left( \frac{1}{s_{Ach}} \sqrt{t_{Dach}} \right) \]
\[ \text{...............(G-7)} \]
At zero time Eq. G-7 becomes

\[
\frac{d\left(\frac{1}{q_{DLh}}\right)}{d\sqrt{t_{DAch}}} = \frac{1}{q^2_{DLh}S_{Ach}^2 \pi^{1.5}}
\]

\[\text{………………..(G-8)}\]

from Eq. F-10 that at small times, \(t_{DAc} = 0\)

\[
q_{DLh} = \frac{1}{2\pi S_{Ach}}
\]

\[\text{…………………..(G-9)}\]

The ratio of the slopes at zero time and late time is given by

\[
\left(\frac{1}{q^2_{DLh}S_{Ach}^2 \pi^{1.5}}\right)
\]

\[\frac{1}{2\pi \sqrt{\pi}}
\]

\[\text{………………...(G-10)}\]

Substituting Eq. G-9 in Eq. G-10

\[
\left(\frac{1}{2\pi S_{Ach}}\right)^2 S_{Ach}^2 \pi^{1.5}
\]

\[\frac{1}{2\pi \sqrt{\pi}}
\]

Which yields

\[
\frac{4\pi^2}{\pi^{1.5} 2\pi \sqrt{\pi}} = \frac{2}{\pi}
\]

\[\text{………………..(G-11)}\]

The ratio of the slopes at zero time and late time is given by \(\frac{2}{\pi}\)
APPENDIX H

DERIVATION OF THE EQUATION FOR THE CONSTANT BOTTOMHOLE PRESSURE EFFECT OF SKIN
(SLAB MATRIX, LINEAR RESERVOIR)

In this section, the equation for the linear dual porosity reservoir (slab matrix, constant pressure inner boundary, closed) with a skin effect will be derived.

The constant rate solution (zero skin) is given by Eq. B-23 in Appendix B as

$$\frac{p_{wDL}}{s\sqrt{sf(s)}} = \frac{2\pi}{s\sqrt{sf(s)}} \left[ \frac{1 + e^{-2\sqrt{sf(s)}\tau_w}}{1 - e^{-2\sqrt{sf(s)}\tau_w}} \right]$$

(H-1)

This was shown in Appendix B to be the same as

$$\frac{p_{wDL}}{s\sqrt{sf(s)}} = \frac{2\pi}{s\sqrt{sf(s)}} \text{Coth} \left( \sqrt{sf(s)} y_{DC} \right)$$

(H-2)

using

$$\text{Coth}(x) = \frac{e^{2x} + 1}{e^{2x} - 1}$$

the addition of skin to Eq. H-2 in Laplace space is given by

$$\frac{p_{wDL}}{s\sqrt{sf(s)}} = \frac{2\pi}{s\sqrt{sf(s)}} \text{Coth} \left( \sqrt{sf(s)} y_{DC} \right) + \frac{2\pi \psi_A}{s}$$

(H-3)

$$\frac{p_{wDL}}{s\sqrt{sf(s)}} = \frac{2\pi \text{Coth} \left( \sqrt{sf(s)} y_{DC} \right) + 2\pi \psi_A \sqrt{sf(s)}}{s\sqrt{sf(s)}}$$

(H-4)

The solution for the constant pressure is obtained by applying the Van Everdingen and Hurst relation\(^{59}\) given by Eq. H-5 to Eq. H-4.

$$q_{DL} = \frac{1}{s^2 p_{wDL}}$$

(H-5)
This results in

\[
\frac{1}{q_{DL}} = \frac{2\pi \operatorname{Coth} \left( \sqrt{sf(s)} y_{De} \right) + 2\pi s_{Ac} \sqrt{sf(s)}}{\sqrt{sf(s)}} \tag{H-6}
\]

Taylor’s series expansion of

\[
\operatorname{Coth}(x) = \frac{1}{x} + \frac{x}{3} - \frac{x^3}{45} + \frac{2x^5}{945} + \ldots \tag{H-7}
\]

Taking first two terms of the series

\[
\operatorname{Coth}(x) = \frac{1}{x} + \frac{x}{3} \tag{H-8}
\]

Thus, in Eq. H-6,

\[
\operatorname{Coth}(\sqrt{sf(s)} y_{De}) = \frac{1}{\sqrt{sf(s)} y_{De}} + \frac{\sqrt{sf(s)} y_{De}}{3} \tag{H-9}
\]

Eq. H-6 becomes

\[
\frac{1}{q_{DL}} = \frac{2\pi \left[ \frac{1}{\sqrt{sf(s)} y_{De}} + \frac{\sqrt{sf(s)} y_{De}}{3} \right] + 2\pi s_{Ac} \sqrt{sf(s)}}{\sqrt{sf(s)}} \tag{H-10}
\]

This yields

\[
\frac{1}{q_{DL}} = \frac{2\pi (3) + 2\pi \left( \sqrt{sf(s)} y_{De}^2 \right) + 2\pi s_{Ac} \sqrt{sf(s) 3y_{De}}}{3sf(s) y_{De}} \tag{H-11}
\]

And thus

\[
q_{DL} = \frac{3sf(s) y_{De}}{2\pi (3) + 2\pi \left( \sqrt{sf(s)} y_{De}^2 \right) + 2\pi s_{Ac} \sqrt{sf(s) 3y_{De}}} \tag{H-12}
\]

For slab matrix,

\[
f(s) = \omega + \sqrt{\frac{\lambda_{Ac}}{3s}} (1 - \omega) \tan \left( \frac{\sqrt{3(1 - \omega)s}}{\lambda_{Ac}} \right) \tag{H-13}
\]
Assume $\omega << \sqrt[3]{\frac{\lambda_{Ac}}{3s}} (1 - \omega) \tanh \left( \frac{3(1 - \omega)s}{\lambda_{Ac}} \right)$ ..........................(H-14)

and $1 - \omega \approx 1$

Approximately for $x > 3$, $\tanh(x) = 1$

Assume $\tanh \left( \frac{3(1 - \omega)s}{\lambda} \right) \approx 1$ ..........................(H-15)

Therefore, Eq. H-13 becomes

$$f(s) = \sqrt[3]{\frac{\lambda_{Ac}}{3s}}$$ ..........................(H-16)

Substituting Eq. H-16 in G-12

$$q_{DL} = \frac{3\sqrt[3]{\lambda_{Ac} s y_{De}}}{2\pi(3) + 2\pi \left( \sqrt[3]{\frac{\lambda_{Ac} s}{3} y_{De}} \right) + 2\pi \sqrt[3]{s \lambda_{Ac} s y_{De} y_{De}^2}}$$ ..........................(H-17)

$$q_{DL} = 3y_{De} \sqrt[3]{\lambda_{Ac}} \frac{\sqrt{s}}{2\pi \left[ 3 + \sqrt[3]{\frac{\lambda_{Ac} s}{3} y_{De}^2 + \lambda_{Ac} s y_{De}} \right]}$$ ..........................(H-18)

$$q_{DL} = 3y_{De} \sqrt[3]{\lambda_{Ac}} \frac{1}{2\pi \left[ 3 + \sqrt[3]{\frac{\lambda_{Ac} s}{3} y_{De}^2 + \lambda_{Ac} s y_{De}} \right]}$$ ..........................(H-19)

$$q_{DL} = 3y_{De} \sqrt[3]{\lambda_{Ac}} \frac{1}{2\pi \left[ 3 + \sqrt[3]{\frac{\lambda_{Ac} s}{3} y_{De}^2 + \lambda_{Ac} s y_{De}} \right]}$$ ..........................(H-20)

or
\[ q_{DL} = 3y_{De} \sqrt{\frac{A_{Ac}}{3}} \frac{1}{2\pi \sqrt{sA}} \left[ \frac{3}{A} + \sqrt{s} \right] \]  \hspace{1cm} \text{(H-21)}

Where \( A = \sqrt{\frac{A_{Ac}}{3}} y_{De}^2 + s_{Ac} \sqrt{\frac{A_{Ac}}{3}} 3y_{De} \)

Inverting Eq. H-21 from Laplace space

\[ q_{DL} = \frac{1}{2\pi} y_{De} \sqrt{\frac{A_{Ac}}{3}} \left[ \frac{3}{A} \right] e^{\left( \frac{y_{De}}{A} \right) t_{DAC} \operatorname{erfc} \left( \frac{3}{A} \sqrt{t_{DAC}} \right)} \]  \hspace{1cm} \text{(H-22)}

It can also be shown as in Appendix F that at small times, \( t_{DAC} = 0 \) Eq. H-22 becomes

\[ q_{DL} = \frac{1}{2\pi} \left( \frac{3}{y_{De} + 3s_{Ac}} \right) \]  \hspace{1cm} \text{(H-23)}

Which yields similar results as Eq. F-11 as described in Chapter VII.

And at large times, \( t_{DAC} = \infty \)

Using first term of asymptotic expansion for \( \operatorname{erfc}(x) \) for large \( x \)

\[ \operatorname{erfc}(x) = \frac{e^{-x^2}}{x \sqrt{\pi}} \]

Eq. H-22 becomes

\[ q_{DL} = \frac{1}{2\pi} y_{De} \sqrt{\frac{A_{Ac}}{3}} \left[ \frac{3}{A} \right] e^{\left( \frac{3}{A} \right) t_{DAC} \operatorname{erfc} \left( \frac{3}{A} \sqrt{t_{DAC}} \right)} \]  \hspace{1cm} \text{(H-24)}

\[ q_{DL} = \frac{1}{2\pi \sqrt{t_{DAC}}} \sqrt{\frac{A_{Ac}}{3}} y_{De} \]  \hspace{1cm} \text{(H-25)}

Which is the expected equation for Region 4 previously given in Eq. C-65.
APPENDIX I

DERIVATION OF EQUATIONS FOR THE BEGINNING OF
CONVERGENCE SKIN STABILIZATION IN LINEAR FLOW

As previously discussed, convergence skin accounts for distortion of the linear flow in the rectangular reservoir to radial flow around the wellbore. The convergence skin develops during radial flow and stabilizes throughout linear flow. In this section equations will be derived for the beginning of this stabilization for both constant rate and constant $p_{wf}$ cases.

I-1 Constant Rate

The equation for the radial flow in a horizontal well is given by

$$ p_{DH} = \frac{1}{2} \ln t_{Dw} + 0.4045 $$

………………………………..(I-1)

Eq. I-1 can also be expressed as

$$ \frac{kL_c \Delta p}{141.2 qB \mu} = \frac{1}{2} \ln \left( \frac{0.00633 k t}{\phi \mu \gamma r_c^2} \right) + 0.4045 $$

………………………………..(I-2)

The equation for linear flow is given by

$$ p_{DL} = 4 \sqrt{\pi \rho \mu_c} + s_c $$

………………………………..(I-3)

where $s_c$ is the convergence skin
Eq. I-3 can also be expressed as

$$k\sqrt{\frac{A_w}{41.2qB\mu}} = 4\sqrt{\frac{0.00633k}{\phi\mu, A_w}} + s_e$$

.........................(I-4)

From Eq. I-2,

$$\frac{k\Delta p}{41.2qB\mu} = \frac{1}{L_w}\left[\frac{1}{2} \ln \left(\frac{0.00633k}{\phi\mu, r^2_e}\right) + 0.4045\right]$$

.........................(I-5)

Differentiating Eq. I-5

$$\frac{d\left(\frac{k\Delta p}{41.2qB\mu}\right)}{dt} = \frac{1}{L_w}\left(\frac{1}{2t}\right)$$

.........................(I-6)

From Eq. I-4,

$$\frac{k\Delta p}{41.2qB\mu} = \frac{1}{\sqrt{A_w}}\left[4\sqrt{\frac{0.00633k}{\phi\mu, A_w}} + s_e\right]$$

.........................(I-7)

Differentiating Eq. I-7

$$\frac{d\left(\frac{k\Delta p}{41.2qB\mu}\right)}{dt} = \frac{1}{\sqrt{A_w}}\left[4\sqrt{\frac{0.00633k}{\phi\mu, A_w}}\right] \frac{1}{2\sqrt{t}}$$

.........................(I-8)

Equate Eqs. I-6 and I-8

$$\frac{1}{2tL_w} = 4\sqrt{\frac{0.00633k}{\phi\mu, A_w}} \frac{1}{2\sqrt{t}}$$

.........................(I-9)

$$\frac{1}{\sqrt{t}} = \frac{L_w}{A_w} 4\sqrt{\frac{0.00633k}{\phi\mu, A_w}}$$

.........................(I-10)
Squaring both sides

\[
\left( \frac{1}{\sqrt{t}} \right)^2 = \frac{L_{\text{w}}}{A_{\text{w}}} \sqrt[4]{\frac{0.00633k}{\phi\mu c_{\text{w}}}}^2 
\]

\[
1 = \frac{L_{\text{w}}^2 16\pi}{A_{\text{w}}} \left( \frac{0.00633kt}{\phi\mu c_{\text{w}} A_{\text{w}}} \right) 
\]

\[
1 = \frac{L_{\text{w}}^2 16\pi}{A_{\text{w}}} t_{DAc} 
\]

Since \( A_{\text{cw}} = 2L_{\text{w}}h \)

Then

\[
1 = \frac{L_{\text{w}}^2 16\pi}{2L_{\text{w}}h} t_{DAc} 
\]

and

\[
t_{DAc} = \frac{h}{8\pi d_{\text{w}}} 
\]

I-2 Constant \( p_{wf} \)

The equation for the radial flow in a horizontal well is given by

\[
\frac{1}{q_{DL}} = \frac{1}{2} \ln t_{p_{bw}} + 0.4045 
\]

Eq. I-16 can also be expressed as

\[
\frac{kL_{\Delta p}}{141.2qB\mu} = \frac{1}{2} \ln \left( \frac{0.00633kt}{\phi\mu c_{w} r_{w}^2} \right) + 0.4045 
\]

The equation for linear flow is given by

\[
\frac{1}{q_{DL}} = 2\pi \sqrt{m_{DAc}} + s_{c} 
\]
Eq. I-18 can also be expressed as

\[
\frac{k_{y}A_{w} \Delta p}{141.2qB \mu} = 2\pi \left( \frac{0.00633 \kappa t}{\phi \mu \gamma A_{w}} \right) + s_{e}
\] .................................(I-19)

Solving Eqs. I-16 to I-19 similarly to the constant rate case given previously yields

\[
\rho_{w} = \frac{h}{2\pi^{3} L_{w}}
\] .................................(I-20)

for the constant \( p_{w} \) case
