#### Abstract

This dissertation focuses on the design and tailoring of dirhodium complexes and the investigation of their structural, spectroscopic and theoretical properties. The variation of the ligands occupying the equatorial (eq) positions results in appreciable changes in the structure and the electronic properties, which renders them suitable for different applications.

The coordination of methyl isocyanide ligands to dirhodium centers bridged by electron-rich formamidinate or orthometalated phosphine ligands led to a family of unprecedented dirhodium complexes of general formula cis- $\left[\mathrm{Rh}_{2}(\mu-\mathrm{L})_{2}\left(\mathrm{CNCH}_{3}\right)_{6}\right]^{2+}(\mathrm{L}=$ bridging ligand). These complexes exhibit unusually long Rh-Rh bond distances and short Rh-C $\left(\mathrm{CH}_{3} \mathrm{NC}\right)$ contacts and exhibit the unexpected bonding situation in which the $R h_{2}\left(\pi^{*}\right)$ levels lie lower in energy than the $\mathrm{Rh}_{2}(\sigma)$ orbitals.

Reactions between cis- $\left[\mathrm{Rh}_{2}(\text { Form })_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]^{2+}($ Form $=$ formamidinate $)$ and the electron accepting chelating diimine ligands $\mathrm{dpq}=$ dipyrido[3,2-f:2', $\left.3^{\prime}-\mathrm{h}\right]-$ quinoxaline, $\mathrm{dppz}=$ dipyrido[3,2-a:2', $\left.3^{\prime}-\mathrm{c}\right]$ phenazine and $\mathrm{dppn}=$ benzo[i]dipyrido[3,2-a:2, $3^{\prime}$ '$\mathrm{h}]$ quinoxaline produce complexes of the general type cis- $\left[\mathrm{Rh}_{2}(\mathrm{Form})_{2}(\mathrm{~N}-\mathrm{N})_{2}\right]^{2+}$ with intriguing photophysical properties. The lowest energy absorption in their electronic absorption spectra is a Ligand-to-Ligand Charger-Transfer (LL'CT) transition which leads to interesting excited state reactivity patterns, most notably water reduction to produce hydrogen.

Three 6-R-hydroxyl-pyridine ligand with different substituents $\left(\mathrm{R}=-\mathrm{CH}_{3},-\mathrm{F},-\mathrm{Cl}\right)$ was selected as a bridging ligand for the series of partial paddlewheel complexes cis-

$\left[\mathrm{Rh}_{2}(\mu-\mathrm{L})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}_{)}\right]^{2+}\right.$. The goal was to probe the effect of the bridging ligand substituents on the lability of the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands. It was shown the substitution rate of the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands is intimately correlated to the electronic characteristics of the bridging ligands with decreased lability occurring in the order of $-\mathrm{F}<-\mathrm{Cl}<-\mathrm{CH}_{3}$, in accord with the stronger trans effect exerted by the more electron donating ligands.

Additional efforts to tune the electronic properties of dirhodium complexes with chelating diimine ligands include the search for new bridging ligands, e.g. $\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]^{-}$. Density Functional Theory (DFT) and Time Dependent (TD) DFT calculations on the synthesized cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}(\mathrm{~N}-\mathrm{N})_{2}\right]^{2+}(\mathrm{N}-\mathrm{N}=\mathrm{dpq}$, dppz, and dppn) complexes indicate that they exhibit very different electronic structures as compared to the dirhodium complexes with formamidinate bridging ligands.

Finally, additional studies were directed at the synthesis of ligands with hydrophilic functional groups to improve the water solubility of the complexes in order to enhance their activity as photodynamic anticancer therapy agents and water reduction photocatalysts.

## ACKNOWLEDGEMENTS

The dissertation presented here would not have been possible without the guidance from Prof. Kim R. Dunbar. She is a great chemist, mentor and I appreciate all of the efforts she put into my education and development as a scientist. I also would like to thank other important members of the research team, namely our talented and dedicated collaborators, Prof. Claudia Turro, Dr. Scott Burya and Dr. Nicholas Leed from The Ohio State University.

The five years spent in the Dunbar group at Texas A\&M University was a great experience. I appreciate the deep friendships I have forged with past and current group members. I would like to give my sincerest thanks to them including Dr. Helen Chifotides, Dr. Ming Fang, Dr. Ian Giles, Dr. Dawid Pinkowicz, Dr. Mohamed Saber, Dr. Heather Southerland, Dr. Zhao-xi Wang, Dr. Yuan-zhu Zhang, Dr. Zhongyue Zhang, Dr. Hanhua Zhao as well as Francisco Birk, Andrew Brown, Amanda David, Jill Frank, David Kempe, Sarah Lane, Jarett Martin, Bruno Pena, Sayan Saha, Codi Sanders, Toby Woods and Xuan Zhang.

I would also like to thank my parents and sister for their unconditional love and my friends for all the encouragement that I have received from them over the years.

## CHAPTER I

## INTRODUCTION

Dirhodium complexes play important roles in various areas of chemical research due to the ease with which their properties can be tuned through rational ligand design. They have been widely used in many different applications such as carbene transfer reaction catalysts, ${ }^{1,2}$ anticancer ${ }^{3-7}$ and photodynamic therapy agents, ${ }^{8-10}$ building blocks for supramolecular arrays, ${ }^{11,12}$ photocatalysts for $\mathrm{H}_{2} \mathrm{O}$ reduction, ${ }^{13-17}$ chromogenic or fluorescence-based sensors for small gaseous molecules such as $\mathrm{NO}^{18}$ and $\mathrm{CO}^{19,20}$ as well as many others. ${ }^{21}$ The most common dirhodium complexes in the literature are those bridged by four carboxylate ligands in the equatorial (eq) positions with two labile ligands occupying the axial (ax) positions as shown in Figure 1.1. Other important bridging ligands include formamidinates, triazenides and acetamides as well as orthometalated phosphines. ${ }^{21}$ One fundamental aspect of the investigation of these dirhodium complexes is the effect of the co-ligands on their electronic structures. Without the perturbation of the ligand field, the $d^{7}-d^{7}$ dirhodium(II,II) center core generally adopts the electronic structure $\sigma^{2} \pi^{4} \delta^{2} \delta^{* 2} \pi^{* 4} \sigma^{0}$, which results in a bond order of 1 (Figure 1.2). ${ }^{21}$ Upon coordination of bridging ligands, such as the carboxylate groups, the interactions between the $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ orbitals with the $\mathrm{p} \pi$ lone pairs on the O atoms results in a destabilization of the $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ orbital. Therefore, the electronic configuration pertaining to the dimetal centers changes to $\sigma^{2} \pi^{4} \delta^{2} \pi^{* 4} \delta^{* 2} \sigma^{0} .{ }^{22}$ In the electronic absorption spectra of $\mathrm{Rh}_{2}(\mu-\mathrm{OCCR})_{4} \bullet 2 \mathrm{~L}\left(\mathrm{~L}=\mathrm{CH}_{3} \mathrm{CN}, \mathrm{CH}_{3} \mathrm{OH}\right.$, pyridine, $\left.\mathrm{PPh}_{3}\right)$, the lowest energy absorption band originates from the $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ to the $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbital
transitions as predicted by many different levels of calculations: this transition is responsible for the wide variety of colors observed for dirhodium paddlewheel complexes. The ax ligands, which are usually kinetically labile, only affect the $\sigma$ type orbitals. ${ }^{21}$ On the other hand, the eq ligands, which are generally more stable as compared to the ax ligands, influence both the $\pi$ and $\delta$ types of orbitals. Generally, the eq ligands are more influential in determining the chemical properties of the complexes. For example, dirhodium complexes with chiral carboxylate groups in the eq positions are demonstrated to be effective for catalyzing the formation of chiral organic molecules. ${ }^{1,2}$ Another good example is that the replacement of the four eq carboxylate groups with more electron-rich formamidinate groups, e.g. $\mathrm{Rh}_{2}(\mathrm{DTolF})_{4}, \mathrm{Rh}_{2}(\mathrm{~F} \text {-form })_{4}$, renders them excellent reducing agents in their excited states and thus useful for the decomposition of harmful organic pollutants in the environment. ${ }^{23}$

Figure 1.2 Depictions of the d orbital overlap for metal-metal bonded units.

In the Dunbar research group, we have long been interested in the design and synthesis of partial paddlewheel dirhodium complexes featuring two cis-oriented bridging groups in the eq positions with the remaining sites being occupied by either monodentate or diimine ligands as shown in Figure 1.3. The exploration of their applications as photodynamic therapy (PDT) agents for cancer treatment and photocatalysts for $\mathrm{H}_{2} \mathrm{O}$ reduction are important aspects of our research in this area.

(b)

Figure 1.3 Structural representation of two types of partial paddlewheel complexes.

## Photodynamic therapy

Photodynamic therapy is a rapidly evolving approach for the treatment of cancer and pre-cancerous conditions. ${ }^{24}$ Typically, the administration of photosensitizers (PS) is followed by selectively irradiating the affected area with low intensity light (preferably ~
$600-850 \mathrm{~nm}$ ). Reactive oxygen species (ROS) such as singlet oxygen, ${ }^{1} \mathrm{O}_{2}$, are generated through an energy transfer process (Figure 1.4). ${ }^{25-27}$ Subsequently, these cytotoxic ROS oxidize various biomolecules including proteins, nucleic acids and lipids. ${ }^{28}$ These reactions eventually lead to cell death in the tumors while only inducing a low level of systematic cytotoxicity towards normal tissues. ${ }^{29-33}$

Figure 1.4 Relaxation pathways for the excited photosensitizer, with the display of the ${ }^{1} \mathrm{O}_{2}$ generation through an energy transfer process.

Successful candidates as photosensitizers in PDT treatment should conform to the following criteria: Firstly, it is preferable for them to be activated by red or near infrared light, for the purpose of deeper tissue penetration as well as producing less damage to the surrounding normal tissues. Secondly, they should be soluble in aqueous solution for easy administration. Thirdly, they should be chemically stable and have very low systemic cytotoxicity in the dark.

Most ${ }^{1} \mathrm{O}_{2}$ sensitizing agents are organic molecules such as those depicted in Figure $1.5,{ }^{34}$ but some transition metal complexes are also very efficient photosensitizers for the generation of ${ }^{1} \mathrm{O}_{2}$ especially $\mathrm{Ru}(\mathrm{II})^{35,36}, \mathrm{Os}(\mathrm{II})^{37}, \operatorname{Ir}(\mathrm{III}){ }^{38,39}, \operatorname{Re}(\mathrm{I}){ }^{40,41}$ compounds. In particular, various $\mathrm{Ru}(\mathrm{II})$ diimine complexes exhibit very strong absorptions in the visible region and can generate ${ }^{1} \mathrm{O}_{2}$ in aerated solutions through a long-lived metal-toligand charge-transfer (MLCT) process with relatively high quantum yields upon light irradiation. ${ }^{42}$ In addition to the sensitization of ${ }^{1} \mathrm{O}_{2}$, the quenching of the excited states of transition metal complexes can be triggered by an electron transfer process (redox event). During this period, the in situ generated products are shown to capable of binding to or oxidizing biomolecules ${ }^{43}$ which provides an advantage for transition metal complexes as effective PDT agents against hypoxic tumors, since their anticancer activity is independent of $\mathrm{O}_{2}$.

Initially, the Turro group explored the photochemistry of $\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4} \bullet 2 \mathrm{~L}$ ( L : alcohol, $\mathrm{PPh}_{3}$, pyridine, THF, $\left.\mathrm{H}_{2} \mathrm{O}\right) .{ }^{44}$ These complexes exhibit long-lived excited states ( $\tau=3.5-5.0 \mu \mathrm{~s}$ ) that can be accessed by visible light irradiation (500-700 nm). Moreover, the bis-aqua species $\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4} \bullet 2 \mathrm{H}_{2} \mathrm{O}$ is able to bind to and photocleave DNA ( $\mathrm{K}_{\mathrm{b}}$ $\left.=4.6 \times 10^{2} \mathrm{M}^{-1}\right)$ in the presence of electron acceptors such as 3-cyano-1-methylpyridinium tetrafluoroborate in its excited state due to the generation of the mixed valence cation $\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4}\right]^{+}$.

Follow-up studies by us involved the incorporation of electron accepting diimine ligands directly into the scaffold of the dirhodium core; these include dpq (dipyrido[3,2-
(a)

(b)

Figure 1.5 Chemical structures of commonly used organic photosensitizers for the generation of ${ }^{1} \mathrm{O}_{2}$.
f: 2', $3^{\prime}$-h]-quinoxaline), dppz (dipyrido[3,2-a:2', $3^{\prime}$ 'cc]phenazine) and dppn ((benzo[i]dipyrido[3,2-a:2', $3^{\prime}$ 'h] quinoxaline) ligands. For example, the compounds cis-$\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})\left(\eta^{1}-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)\left(\mathrm{CH}_{3} \mathrm{OH}\right)\right]^{+}$and $\quad c i s-\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})_{2}\right]^{2+}$ cause direct pUC18 plasmid cleavage in vitro upon the irradiation with visible light ( $\lambda_{\text {irr }}>$ $395 \mathrm{~nm}, 15 \mathrm{~min}$ ), resulting in the formation of nicked circular DNA (Figure 1.6). ${ }^{45-47}$ One advantage afforded by the aforementioned complexes as compared to the commonly used organic photosensitizers is that the photocleavage of DNA occurs in the absence of $\mathrm{O}_{2}$. In addition, cell studies showed a 3.4-fold increase of the cytotoxicity for cis-[ $\mathrm{Rh}_{2}(\mu-$ $\left.\left.\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})_{2}\right]^{2+}$ towards human skin cells (Hs-27) upon irradiation (with 400-700 nm light for 30 min ). Moreover, the series of dirhodium-dppn complexes, e.g. cis-$\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})(\mathrm{dppn})\right]^{2+}$ and cis- $\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppn})_{2}\right]^{2+}$ were reported to
exhibit a 21- and 24- fold increase of cytotoxicity towards Hs-27 human skin fibroblasts upon irradiation with visible light ( $\lambda_{\text {irr }}>375 \mathrm{~nm}, 30 \mathrm{~min}$ ) respectively as compared to their activities in the dark. ${ }^{48}$

Figure 1.6 Ethidium bromide stained agarose gels (2\%) of $100 \mu \mathrm{M} \mathrm{pUC} 18$ plasmid in the presence of $20 \mu \mathrm{M}$ cis- $\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})_{2}\right]^{2+}$ in 5 mM Tris, $50 \mathrm{mM} \mathrm{NaCl}(\mathrm{pH}$ $=7.5$ ) buffer solution irradiated with $\lambda_{\text {irr }}>395 \mathrm{~nm}$ light: (a) lane 1 , plasmid only, dark; lane 2, plasmid + SmaI; lane 3, plasmid + 1, dark; lane 4, plasmid + 1, irr 15 min ; lane 5, plasmid + compound, dark; lane 6, plasmid + compound, irr for 15 min ; (b) lane 1 , plasmid only, dark; lane 2, plasmid only, irr for 20 min ; lane 3 , plasmid + compound, dark; lane 4 , plasmid + compound, irr for 20 min , air; lane 5, plasmid + compound, irr for $20 \mathrm{~min}, 50 \% \mathrm{D}_{2} \mathrm{O}$; lane 6, plasmid + compound, irr for 20 min , under $\mathrm{N}_{2}$; lane 7, plasmid + compound, irr for 20 min , freeze-pump-thaw.

Another important partial paddlewheel dirhodium (II,II) complex with excellent potential as a PDT agent is depicted in Figure 1.3a, namely $c i s-\left[\mathrm{Rh}_{2}(\mu-\right.$ $\left.\left.\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} .{ }^{8}$ Irradiation of this compound with visible light (400-700 nm ) for 30 minutes induced cell damage towards the $\mathrm{Hs}-27$ human skin cells with $\mathrm{LC}_{50}$ values decreasing from $410 \pm 9$ to $12 \pm 2 \mu \mathrm{M}$. The 34 -fold increase of toxicity upon irradiation is attributed to the generation of the photoactive species $c i s-\left[\mathrm{Rh}_{2}(\mu\right.$ $\left.\left.\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$, which binds to double-stranded DNA (ds-DNA) as evidenced by the gel mobility studies shown in Figure 1.7. The generation of this active species occurs via a one-photon process, leading to the initial photosubstitution of one eq $\mathrm{CH}_{3} \mathrm{CN}$ ligand, followed by the loss of a second eq $\mathrm{CH}_{3} \mathrm{CN}$ ligand bound to the same metal center in a dark reaction. ${ }^{9}$ Time-dependent Density Functional Theory (TD-DFT) calculations for three different isomers of cis- $\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ were performed, indicating the charge-transfer process in the excited states involving placing electron density onto the $\sigma^{*}$ molecular orbital between Rh and the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands. This explains the facile dissociation of two eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands upon irradiation. The quantum yield for this exchange process is also dependent on the power of the light used during the photolysis experiment, which is characteristic of the excited states of transition metal complexes. Of even greater interest, the increase of cytotoxicity is also independent of $\mathrm{O}_{2}$.

Figure 1.7 Imaged ethidium bromide stained agarose gel of $50 \mu \mathrm{M}$ linearized pUC 18 plasmid ( 10 mM phosphate, $\mathrm{pH}=7.5$ ) in the presence of various concentrations of cis-$\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ (a) irradiated $(\lambda>455 \mathrm{~nm})$ and (b) incubated in the dark at $25^{\circ} \mathrm{C}$ for 20 min ; lanes 1 and 8: DNA molecular weight standard ( 1 kb , Sigma); lanes 2 and 7: linearized plasmid alone; lanes 3-6: [DNA bp]/[complex] ) 100, 20, 10, 5.

## Photocatalysis for $\mathrm{H}_{2} \mathrm{O}$ reduction

The environmental issues and impending energy crisis arising from the rapid consumption of traditional fossil fuels has led to an upsurgence in research aimed at developing clean and renewable energy resources. ${ }^{49}$ Utilization of abundant sunlight is an attractive alternative solution to these problems but one major challenge lies in its storage for further use. ${ }^{50-51}$ One simple and effective way is to convert it into chemical bonds, such as the photocatalytic reduction of $\mathrm{H}_{2} \mathrm{O}$ to produce $\mathrm{H}_{2}$ as a clean fuel. Nature provides elegant catalytic systems for this purpose in the form of hydrogenases whose active sites are composed of dinuclear thiolate bridged nickel and/or iron complexes with ancillary CO and $\mathrm{CN}^{-}$ligands. ${ }^{52}$ Their instability under ambient conditions ${ }^{53,54}$ requires further development using more stable coordination complexes.

The photocatalytic systems for $\mathrm{H}_{2} \mathrm{O}$ reduction studied to date are typically composed of multiple parts: a photosensitizer to harvest photons, a sacrificial electron donor to provide the electron source, the photocatalyst, and a redox-active electron mediator couple to effect electron transfer between the photosensitizer and the photocatalyst under most conditions. ${ }^{55}$ The commonly used photosensitizers include complexes of $\mathrm{Ru}(\mathrm{II}),{ }^{56}$ $\operatorname{Pt}(\mathrm{II}),{ }^{57,58} \operatorname{Re}(\mathrm{I}),{ }^{59,60} \operatorname{Ir}(\mathrm{III}){ }^{61}$ as well as some newly reported $\mathrm{Cu}(\mathrm{I})$ complexes. ${ }^{62}$ The catalysts used with these sensitizers are generally based on $\mathrm{Co}(\mathrm{II}),{ }^{63} \mathrm{Ni}(\mathrm{II}),{ }^{64} \mathrm{Mo}(\mathrm{III}),{ }^{65}$ and $\mathrm{Fe}(\mathrm{II}) .{ }^{66}$ These systems, however, require further improvement since the additional charge-transfer step between the photosensitizer and the catalysts reduces the efficiency of the $\mathrm{H}^{+}$reduction process.

Two different strategies have been developed to address this issue. The first one is the incorporation of the photosensitizer directly into the water reduction catalyst. One typical example in this category is the tethering of a $\operatorname{Ir}(\mathrm{III})$ photosensitizer to the cobaloxime catalyst (Figure 1.8), leading to a turnover number (TON) of 210 after 15 h irradiation (TOF $=42 \mathrm{~h}^{-1}$ ) for the catalytic system ( 600 equivalents of $\mathrm{Et}_{3} \mathrm{~N}$ as sacrificial electron donor and 600 equivalents of $\mathrm{Et}_{3} \mathrm{NH}^{+}$as the proton source). ${ }^{67}$ This result represents a better performance as compared to a TON of 160 under the same conditions for the multicomponent system.

Another strategy is to design transition metal complexes that can act as both a photosensitizer and a $\mathrm{H}^{+}$reduction catalyst, such as $\mathrm{LRh}(0)_{2}(\mathrm{dfpma})_{3} \mathrm{~L}$ or the mixedvalence compound $\mathrm{LRh}(0) \mathrm{Rh}(\mathrm{II})(\mathrm{dfpma})_{3} \mathrm{X}_{2}$ (Figure 1.9a) $\left(\mathrm{dfpma}=\mathrm{MeN}\left(\mathrm{PF}_{2}\right)_{2}, \mathrm{~L}=\mathrm{CO}\right.$, $\left.\mathrm{PR}_{3}, \mathrm{CNR}, \mathrm{X}=\mathrm{Cl}, \mathrm{Br}\right)$ studied by Nocera and coworkers. ${ }^{68-70}$ Important progress has been made by the same group of researchers, including the design of complexes with more oxidizing dimetal centers, such as the homobimetallic bioctahedral $d^{7}-d^{7}$ complex $\mathrm{Pt}_{2}($ III,III $)(\mathrm{tfepma})_{2} \mathrm{Cl}_{6} \quad$ (tfepma $\left.=\operatorname{MeN}\left[\mathrm{P}\left(\mathrm{OCH}_{2} \mathrm{CF}_{3}\right)_{2}\right]_{2}\right) \quad$ (Figure 1.9 b ) which photoeliminates $\mathrm{Cl}_{2}$ in the excited state. The quantum yield for the bis-platinum complex reaches $38 \%$ as compared to a quantum yield of $<1 \%$ for the aforementioned dirhodium complexes. ${ }^{71}$

## CHAPTER II

## COMPREHENSIVE INVESTIGATION OF A FAMILY OF UNUSUAL PARTIAL PADDLEWHEEL DIRHODIUM ISOCYANIDE COMPLEXES**

## Introduction

Dirhodium complexes are important members of the large family of metal-metal bonded compounds. One central issue for research pertaining to dirhodium complexes is the modification of the equatorial ligands to tune properties. For example, cis$\left[\mathrm{Rh}_{2}\left(\mathrm{DTolF}_{2}\left(\mathrm{O}_{2} \mathrm{CCF}_{3}\right)_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O} \quad\left([\mathrm{DTolF}]^{-}=\right.\right.$p-ditolylformamidinate $)$exhibits comparable anticancer activity to the widely used chemotherapy drug cisplatin but with reduced toxicities, ${ }^{72}$ and dirhodium complexes with orthometalated phosphines and other $\mathrm{N}, \mathrm{O}-$ donor type bridging groups are excellent catalysts for enantioselective $\mathrm{C}-\mathrm{H}$ insertion reactions of $\alpha$-diazo compounds via metallocarbene intermediates. ${ }^{1,2,73}$ In a similar vein, the progressive replacement of the acetate groups by the more electron-rich acetamidate ligands in the series of $\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4-n}\left(\mathrm{HNCOCH}_{3}\right)_{n}(\mathrm{n}=1-4)$ increases the electron density on the dirhodium core and thus raises the energy of the HOMO orbital rendering the substituted derivatives better electron donors than $\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4}{ }^{74,75}$ In fact, $\mathrm{Rh}_{2}\left(\mathrm{HNCOCH}_{3}\right)_{4}, \quad \mathrm{Rh}_{2}(\mathrm{DPhF})_{4}{ }^{76}$ (DPhF: N,N'-diphenylformamidinate) and $\mathrm{Rh}_{2}(\mathrm{DTolF})_{4}$ form stable complexes with CO at room temperature, ${ }^{77}$ as compared to $\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4}(\mathrm{CO})_{2}$ which can be isolated only at low temperatures. ${ }^{22}$ Of special interest in this vein is that a dirhodium compound with two orthometalated phosphine

[^0]groups has been recently applied as a sensitive and selective chromogenic CO sensor. ${ }^{19,20}$ These phosphine ligands render the dirhodium unit more electron-rich, leading to enhanced $\pi$-backbonding to the CO ligand. ${ }^{78-80}$

Of specific relevance to the present study is the use of isocyanide ligands in transition metal chemistry. ${ }^{81}$ Reports of $\mathrm{Rh}_{2}$ (II,II) metal-metal bonded isocyanide complexes are quite scarce, ${ }^{82,83}$ however, due to the ease of reduction to $\mathrm{Rh}(\mathrm{I})$ species, and, in the case of other metal-metal bonded dimetallic cores such as $\mathrm{Cr}_{2}$ (II,II), $\mathrm{Mo}_{2}$ (II,II), $\mathrm{W}_{2}$ (II,II) and $\mathrm{Re}_{2}$ (III, III), cleavage of the dimetal unit has been found to be facile. ${ }^{84-88}$ Pioneering studies by Gray et al. in the late 1970s led to an exciting discovery involving dirhodium isocyanide compounds, viz., oxidative addition of halogens to the $\mathrm{Rh}(\mathrm{I})$ isocyanide precursors $\mathrm{Rh}_{2}\left[\mathrm{CN}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{NC}\right]_{4}{ }^{2+89}$ and $\left[\mathrm{Rh}_{2}(\mathrm{TMB})_{4}\right]^{2+}$, upon irradiation at 550 nm in strongly acidic HCl solutions, to form $\mathrm{H}_{2}$ and the dirhodium(II,II) containing salts $\left[\mathrm{Rh}_{2}\left[\mathrm{CN}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{NC}_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}_{2}{ }^{90}\right.$ and $\left[\mathrm{Rh}_{2}(\mathrm{TMB})_{4} \mathrm{Cl}_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}(\mathrm{TMB}=2,5$-di-isocyano-2,5dimethylhexane) ${ }^{91}$, respectively. More recently, Nocera and coworkers have made important progress in developing dirhodium-based photocatalysts bearing isocyanide ligands. ${ }^{15-17}$ From the mechanistic studies, they found that $\mathrm{L}-\mathrm{Rh}(0)-\mathrm{Rh}(\mathrm{II})-\mathrm{X}_{2}$ or $\mathrm{L}-$ $\mathrm{Rh}(0)-\mathrm{Rh}(0)-\mathrm{L}$ complexes $\left(\mathrm{L}=\mathrm{CO}, \mathrm{PR}_{3}, \mathrm{CNR} ; \mathrm{X}=\mathrm{Br}, \mathrm{Cl}\right)$ lead to $\mathrm{Rh}(\mathrm{II})-\mathrm{Rh}(\mathrm{II})$ species, which are responsible for the photocatalytic production of $\mathrm{H}_{2}$ or the reduction of $\mathrm{O}_{2}$ in HX solutions.

The promising chemistry that has been reported over the years with a handful of $\mathrm{Rh}_{2}$ (III,II) isocyanide complexes with halogens in the axial positions notwithstanding, ${ }^{92-}$ ${ }^{100}$ this chemistry, especially with monodentate isocyanide ligands, remains relatively unexplored due to the challenge of preventing reduction to $\mathrm{Rh}(\mathrm{I})$ mononuclear products. In this chapter several members of an entirely new type of metal-metal bonded complex (5-8) are described which feature two cis strong $\sigma$-donating bridging groups $p$ ditolylformamidinate (a), p-difluorophenylformamidinate (b), p-ditolyltriazenide (c) or orthometalated phosphine (d) and methyl isocyanide ligands in the axial and the other four equatorial positions (Scheme 2.1). The isocyanide series of dirhodium complexes $\mathbf{5}$ 8 (Scheme 2.1, $\mathrm{L}=\mathrm{CH}_{3} \mathrm{NC}$ ) and the corresponding acetonitrile analogs 1-4 (Scheme 2.1, $\mathrm{L}=\mathrm{CH}_{3} \mathrm{CN}$ ), which are synthetic precursors for the methyl isocyanide derivatives, were fully characterized by X-ray crystallography, ${ }^{1} \mathrm{H},{ }^{31} \mathrm{P}$ NMR, electronic and infrared spectroscopies as well as electrochemical studies. Noteworthy structural and spectroscopic features of 5-8 were probed in a comprehensive fashion as compared to 14. In particular, compound 8 (Scheme $2.1, \mathrm{~L}=\mathrm{CH}_{3} \mathrm{NC}$ ) exhibits nearly the same ax and eq Rh-C $\left(\mathrm{CH}_{3} \mathrm{NC}\right)$ distances, which, to our knowledge, is unprecedented for dirhodium compounds. The experimental data for $\mathbf{1 - 8}$ were corroborated by DFT and TD-DFT calculations, which also unearthed notable findings that are detailed herein.

## Experimental section

## Starting materials

The precursor $[\mathrm{RhCl}(\mathrm{COD})]_{2}$ (COD: cycloocta-1,5-diene) was purchased from Pressure Chemicals whereas $\left[\mathrm{FeCp}_{2}\right]\left[\mathrm{BF}_{4}\right]$ and $\left[\mathrm{RhCl}(\mathrm{CO})_{2}\right]_{2}$ were purchased from SigmaAldrich; all reagents were used as received. Methyl isocyanide ${ }^{101},[\mathrm{Rh}(\mathrm{F} \text {-form })(\mathrm{COD})]_{2},{ }^{102}$ and $\left[\mathrm{Rh}(\mathrm{NNN})(\mathrm{CO})_{2}\right]_{2}$ and NNNH (ditolyltriazene) ${ }^{103}$ were prepared by slightly modified published procedures. The compounds cis$\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}{ }^{104}(\mathbf{1})$ and cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}^{105}$ (4) were synthesized according to published methods. The acetonitrile solvent was pre-dried over $3 \AA$ molecular sieves and distilled under $\mathrm{N}_{2}$ whereas dichloromethane was pre-dried over $4 \AA$ molecular sieves and distilled over $\mathrm{P}_{2} \mathrm{O}_{5}$ under $\mathrm{N}_{2}$. All manipulations were conducted using standard Schlenk-line techniques unless otherwise stated. The work-up and isolation of the products, however, were conducted in air.

Preparation of cis-[ $\left.\mathrm{Rh}_{2}(\mathrm{~F} \text {-form })_{\mathbf{2}}\left(\mathbf{C H}_{\mathbf{3}} \mathbf{C N}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ (2). A quantity of $[\mathrm{Rh}(\mathrm{F}-$ form $)(\mathrm{COD})]_{2}(120 \mathrm{mg}, 0.14 \mathrm{mmol})$ was added to 30 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{CH}_{3} \mathrm{CN}(1: 1 \mathrm{v} / \mathrm{v})$ and the red/orange solution was stirred until the solid was fully dissolved. Subsequently $\mathrm{AgBF}_{4}(106 \mathrm{mg}, 0.55 \mathrm{mmol})$ was added to the solution which led to a gradual color change to green. The reaction solution was stirred in the dark at room temperature for 24 h and then filtered through Celite ${ }^{\circledR}$ to remove finely divided silver particles. The filtrate was evaporated to dryness and redissolved in 10 mL of $\mathrm{CH}_{3} \mathrm{CN}$ (red solution). The addition of diethyl ether ( 40 mL ) induced precipitation of the desired product. Yield: $75 \%$ (112 mg, 0.10 mmol ). Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{36} \mathrm{~N}_{10} \mathrm{~B}_{2} \mathrm{~F}_{12} \mathrm{Rh}_{2} \cdot 3 \mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{C}, 36.64$; N ,
10.43 ; H, $3.15 \%$. Found: C, 36.67 ; N, $10.33 ; \mathrm{H}, 3.11 \% .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}-d_{3}\right), \delta(\mathrm{ppm})$ : 2.53 (s, eq $\mathrm{CH}_{3} \mathrm{CN}$ ), 7.05 (m, p-difluorophenyl), $7.49\left(\mathrm{t}, \mathrm{NCHN},{ }^{3} \mathrm{~J}_{\mathrm{Rh}-\mathrm{H}}=4 \mathrm{~Hz}\right.$ ).

Preparation of cis-[ $\left.\mathbf{R h}_{\mathbf{2}}(\mathbf{N N N})_{\mathbf{2}}\left(\mathbf{C H}_{\mathbf{3}} \mathbf{C N}\right)_{\mathbf{6}}\right]\left[\mathbf{B F}_{4}\right]_{\mathbf{2}}$ (3). Samples of $\left[\mathrm{RhCl}(\mathrm{CO})_{2}\right]_{2}(50 \mathrm{mg}$, $0.13 \mathrm{mmol})$ and $58 \mathrm{mg}(0.26 \mathrm{mmol})$ of NNNH were added to dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(25 \mathrm{~mL})$. After dissolution of the two reactants, $\mathrm{NEt}_{3}(45 \mu \mathrm{~L}, 0.32 \mathrm{mmol})$ was added to the solution which was accompanied by an instantaneous color change from yellow to red. The reaction solution was stirred under $\mathrm{N}_{2}$ for 20 minutes and evaporated to dryness. The product $\left[\mathrm{Rh}(\mathrm{NNN})(\mathrm{CO})_{2}\right]_{2}$ was extracted with hexanes $(3 \times 10 \mathrm{~mL})$. The three extracts of hexanes were combined, reduced to dryness and re-dissolved in dry $\mathrm{CH}_{3} \mathrm{CN}(30 \mathrm{~mL})$. To this solution was added $\left[\mathrm{FeCp}_{2}\right]\left[\mathrm{BF}_{4}\right](70 \mathrm{mg}, 0.26 \mathrm{mmol})$ and the mixture was refluxed for 48 h . The solution was filtered and concentrated to 5 mL and diethyl ether was added to precipitate the product. Yield: $81 \mathrm{mg}, 60 \%$. X-ray quality crystals were obtained by slow diffusion of diethyl ether into an acetonitrile solution of the product. Anal. Calcd for $\mathrm{C}_{40} \mathrm{H}_{46} \mathrm{~N}_{12} \mathrm{~B}_{2} \mathrm{~F}_{8} \mathrm{Rh}_{2} \cdot 5 \mathrm{CH}_{2} \mathrm{Cl}_{2} \cdot \mathrm{H}_{2} \mathrm{O}: \mathrm{C}, 35.60 ; \mathrm{N}, 11.08 ; \mathrm{H}, 3.85 \%$. Found: $\mathrm{C}, 35.71 ; \mathrm{N}, 11.07 ; \mathrm{H}, 3.91 \% .{ }^{1} \mathrm{H}$ NMR in $\left(\mathrm{CD}_{3} \mathrm{CN}-d_{3}\right), \delta(\mathrm{ppm}): 2.31\left(\mathrm{~s}, \mathrm{CH}_{3}\right.$, tolyl), 2.52 ( s , eq $\mathrm{CH}_{3} \mathrm{CN}$ ), 7.11 ( m , tolyl-triazenide).

Preparation of $\boldsymbol{c i s}$ - $\left[\mathbf{R h}_{\mathbf{2}}(\mathbf{D T o l F})_{\mathbf{2}}\left(\mathbf{C N C H}_{\mathbf{3}}\right)_{\mathbf{6}}\right]\left[\mathbf{B F}_{\mathbf{4}}\right]_{\mathbf{2}} \mathbf{( 5 )}$. Methyl isocyanide ( $39 \mu \mathrm{~L}, 0.75$ $\mathrm{mmol})$ was added to a reddish/brown slurry of cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}(80$ $\mathrm{mg}, 0.075 \mathrm{mmol})$ in $\mathrm{CH}_{3} \mathrm{CN}(10 \mathrm{~mL})$ which led to a color change to yellow. The solution was stirred under $\mathrm{N}_{2}$ for 8 h , concentrated to 5 mL and then treated with an excess of diethyl ether to induce precipitation of the product. The filtered solid was washed with diethyl ether ( $3 \times 5 \mathrm{~mL}$ ) and dried overnight under vacuum. Yield $83 \%$ ( $66 \mathrm{mg}, 0.062$
mmol). X-ray quality crystals were obtained by slow diffusion of diethyl ether into a solution of the product in acetonitrile. Anal. Calcd for $\mathrm{C}_{42} \mathrm{H}_{48} \mathrm{~N}_{10} \mathrm{~B}_{2} \mathrm{~F}_{8} \mathrm{Rh}_{2} \cdot \mathrm{CH}_{3} \mathrm{CN} \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}$ : C, 45.07; N, 12.86; H, $4.46 \%$. ## Instrumentation

The ${ }^{1} \mathrm{H}$ NMR spectra were collected on a 300 MHz Varian spectrometer and the chemical shifts were referenced relative to the residual proton impurities of the deuterated solvent $\left(\mathrm{CD}_{3} \mathrm{CN}, d_{3}\right)$. Electronic absorption spectra were obtained on a Shimadzu UV-1601PC spectrophotometer. Infrared spectra were recorded as Nujol mulls between KBr plates with a Nicolet Nexus 470 FT-IR spectrometer. Elemental analyses were performed by Atlantic Microlab, Inc. Electrospray mass spectral data were obtained in the Laboratory for Biological Mass Spectrometry at Texas A\&M University using a PE Sciex (Concord, Ontario, Canada) API Qstar Pulsar with an Ionwerks time-to-digital converter, TDCx4, for data recording. Electrochemical data were collected using a CH Instruments analyzer in dry $\mathrm{CH}_{3} \mathrm{CN}$. The working electrode was a BAS Pt disk electrode, the reference electrode was $\mathrm{Ag} / \mathrm{AgCl}$, and the counter electrode was a Pt wire. X-ray data sets for $\mathbf{2 , 3}, \mathbf{5 - 8}$ were collected on a Bruker CCD APEX diffractometer with graphite monochromated Mo K $\alpha$ radiation $(\lambda=0.71073 \AA)$.

## Methods

Cyclic voltammetric measurements were performed at 298 K in $\mathrm{CH}_{3} \mathrm{CN}$ with 0.1 M tetra- $n$-butylammonium hexafluorophosphate $\left(\left[\mathrm{n}-\mathrm{Bu}_{4} \mathrm{~N}\right]\left[\mathrm{PF}_{6}\right]\right)$ as the supporting electrolyte. The $E_{1 / 2}$ values were referenced to the $\mathrm{Ag} / \mathrm{AgCl}$ electrode without correction for the junction potentials $\left[E_{1 / 2}=\left(E_{\mathrm{p}, \mathrm{a}}+E_{\mathrm{p}, \mathrm{c}}\right) / 2\right]$. The $\mathrm{FeCp}_{2} /\left[\mathrm{FeCp}_{2}\right]^{+}$couple is located at $E_{1 / 2}=+0.45 \mathrm{~V}$ in $\mathrm{CH}_{3} \mathrm{CN}$ at the same conditions used for the compounds.

The molecular and electronic structure calculations were performed by Density Functional Theory (DFT) methods using the Gaussian09 (G09) program package. ${ }^{106}$ The

MPW1PW91 correlation and exchange functionals ${ }^{107-109}$ were used with the Stuttgart RSC 1997 Electron Core Potential (ECP) ${ }^{110}$ basis set for the Rh atoms and the 6-31G (d') basis set for the C, N, F, H atoms. ${ }^{111,112}$ Geometric parameters were taken from the crystal structures without the $\left[\mathrm{BF}_{4}\right]^{-}$anions, and were used as the starting point for the simulations, followed by frequency calculations to evaluate the full optimization. TimeDependent Density Functional Theory (TD-DFT) ${ }^{113-119}$ calculations were conducted in the gas phase as well as using the polarized continuum model (PCM) with $\mathrm{CH}_{3} \mathrm{CN}$ as the solvent, ${ }^{120,121}$ based on the optimized singlet ground state geometry. The first twenty lowest singlet-to-singlet excitations were included for both the gas phase and solvation models in the singlet state calculations. The molecular orbitals were plotted with the graphic software 'agui' ${ }^{122}$ with an iso-value $=0.04$. Detailed analysis of the compositions of the orbitals was obtained through the Chemissian program http://www.chemissian.com.

A hemisphere of crystallographic data was collected by a combination of four sets of exposure. Each set had a different $\varphi$ angle for the crystals, and each exposure covered $0.3^{\circ}$ in $\omega$. The exposure time for $\mathbf{5 - 8}$ was 10 s whereas for $\mathbf{2}, \mathbf{3}$, it was 20 s . Crystal decay was monitored by analyzing duplicate reflections and was found to be less than $1 \%$, therefore no decay correction was applied. The frames were integrated with the Bruker AXS SAINT Software package, ${ }^{123}$ and the data were corrected for absorption using the SADABS program in the same software package. ${ }^{124}$ The structures were solved by direct methods and refined by using X-SEED, ${ }^{125-127}$ a graphical interface to the SHELX97 suite
of programs. ${ }^{128}$ In the final cycles of the refinement, all atoms except for hydrogen were refined anisotropically.

## Results

## Synthesis

Compounds $\mathbf{1 - 3}$ were prepared by oxidation of $\mathrm{Rh}(\mathrm{I})$ starting materials; $\mathbf{1}$ and $\mathbf{2}$ were synthesized by similar procedures whereas $[\mathrm{Rh}(\mathrm{F}-\text { form })(\mathrm{COD})]_{2}$, which is a precursor to 2, was synthesized according to a method similar to $[\mathrm{Rh}(\mathrm{DTolF})(\mathrm{COD})]_{2}$. Subsequently, $[\mathrm{Rh}(\mathrm{F} \text {-form })(\mathrm{COD})]_{2}$ was reacted with an excess of $\mathrm{AgBF}_{4}$ to afford $\mathbf{2}$ (Eq. 2.1):

Eq. 2.1

The compound $\left[\mathrm{Rh}(\mathrm{NNN})(\mathrm{CO})_{2}\right]_{2}$, which is a precursor to 3 , was prepared by a slightly modified published procedure. As shown in Eq. 2.2, a slight excess of $\left[\mathrm{FeCp}_{2}\right]\left[\mathrm{BF}_{4}\right]$ was used to oxidize $\mathrm{Rh}(\mathrm{I})$ to $\mathrm{Rh}(\mathrm{II})$ to afford $\mathbf{3}$ and ferrocene, which was removed by excess amount of diethyl ether.

$$
\begin{equation*}
\left.\left[\mathrm{Rh}(\mathrm{NNN})(\mathrm{CO})_{2}\right]_{2} \xrightarrow[\mathrm{CH}_{3} \mathrm{CN}]{\left[\mathrm{Fe}(\mathrm{Cp})_{2}\right]\left[\mathrm{BF}_{4}\right]} \text { cis-[ } \mathrm{Rh}_{2}(\mathrm{NNN})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} \tag{Eq. 2.2}
\end{equation*}
$$

The corresponding methyl isocyanide analogs 5-8 were prepared by substitution of the monodentate acetonitrile ligands with methyl isocyanide in 1-4. An excess of $\mathrm{CH}_{3} \mathrm{NC}$ was used during the syntheses of the methyl isocyanide analogs 5-8. The general synthetic route for 5-7 is depicted in Eq. 2.3:
cis- $\left[\mathrm{Rh}_{2}(\mathrm{~N}-\mathrm{N})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} \xrightarrow[\substack{\mathrm{CH}_{3} \mathrm{CN} \\ \text { r.t. }}]{10 \text { equ. } \mathrm{CH}_{3} \mathrm{NC}}$ cis- $\left[\mathrm{Rh}_{2}(\mathrm{~N}-\mathrm{N})_{2}\left(\mathrm{CNCH}_{3}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} \quad$ Eq. 2.3

A characteristic color change occurs from reddish/brown to light yellow upon addition of methyl isocyanide to solutions of 1-3 to afford 5-7, respectively. Unlike compounds 5-7, prolonged stirring of $\mathbf{8}$ in $\mathrm{CH}_{3} \mathrm{CN}$ leads to product decomposition as evidenced by ${ }^{1} \mathrm{H}$-NMR spectroscopy (vide infra) therefore $\mathbf{8}$ was prepared by stirring $\mathbf{4}$ under $\mathrm{N}_{2}$ for 30 min only, in the presence of $\mathrm{CH}_{3} \mathrm{NC}$.

## X-ray crystallographic studies

The crystal parameters and information pertaining to the data collection and refinement for 2, $\mathbf{3}$ and 5-8 are summarized in Table 2.1.
cis-[ $\left.\left.\mathbf{R h}_{\mathbf{2}}(\mathbf{F} \text {-form })_{\mathbf{2}}\left(\mathbf{C H}_{3} \mathbf{C N}\right)_{6}\right)\right]\left[\mathrm{BF}_{4}\right]_{2} \cdot \mathbf{E t}_{2} \mathbf{O}\left(\mathbf{2} \cdot \mathbf{E t}_{\mathbf{2}} \mathbf{O}\right)$, (2). A thermal ellipsoid plot of the cationic unit in $\mathbf{2}$ is shown in Figure 2.1. The dirhodium unit is bridged by two [F-form] ${ }^{-}$ ligands in a cis arrangement with six $\mathrm{CH}_{3} \mathrm{CN}$ ligands occupying the remaining Rh (II) coordination sites. The Rh-Rh bond distance is $2.571(1) \AA$ which is comparable to 1 and the compounds cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{bpy})\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}\right]\left[\mathrm{BF}_{4}\right]_{2}$ and cis$\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{bpy})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)\right]\left[\mathrm{BF}_{4}\right]_{2} .{ }^{129}$ The Rh-N $[\mathrm{F}-\text { form }]^{-}$and $\mathrm{Rh}-\mathrm{N}$ (eq $\mathrm{CH}_{3} \mathrm{CN}$ ) distances are in the ranges 2.024(4)-2.052(5) and 2.032(5)-2.043(5) $\AA$, respectively. The previous distances are similar to $\mathbf{1}$ but longer than the corresponding distances in cis$\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$. ${ }^{130}$ As in the case of $\mathbf{1}$ and cis$\left[\mathrm{Ir}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2},{ }^{131}$ a splaying of the four eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands occurs. The [F-form] groups are twisted by $18.0(2)^{\circ}$ from the eclipsed conformation and the eq $\mathrm{CH}_{3} \mathrm{CN}$ groups are twisted by $22.8(2)^{\circ}$ due to the steric constraints imposed by the bridging ligands.

Figure 2.1 Thermal ellipsoid plot for the cationic unit in 2 at the 50\% probability level.
cis- $\left[\mathbf{R h}_{\mathbf{2}}(\mathbf{N N N})_{\mathbf{2}}\left(\mathbf{C H}_{\mathbf{3}} \mathbf{C N}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$, (3). The cationic unit in $\mathbf{3}$ is shown in Figure 2.2. The Rh-Rh bond distance is $2.5135(9) \AA$, which is slightly shorter than the $\mathrm{Rh}-\mathrm{Rh}$ distance in cis-[Rh $\left.\left.\mathrm{R}_{2}(\mathrm{NNN})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}(\mathrm{bpy})\right]\left[\mathrm{PF}_{6}\right]_{2} \quad(2.534(2) \AA)^{\circ}\right){ }^{132}$ The Rh-N (eq $\mathrm{CH}_{3} \mathrm{CN}$ ) bond distances are in the range 1.996(7)-2.024(6) $\AA$ and are comparable to the corresponding distances in 1, 2 and cis- $\left[\mathrm{Rh}_{2}(\mathrm{NNN})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}(\mathrm{bpy})\right]\left[\mathrm{PF}_{6}\right]_{2}$. The Rh-N ([NNN $]^{-}$) bond distances are in the range 2.011(6)-2.024(6) $\AA$, and are slightly shorter than the corresponding ones in 1, 2 and $\mathrm{Rh}-\mathrm{N}$ ( N trans to eq bpy in [NNN] ${ }^{-}$) and comparable to the $\mathrm{Rh}-\mathrm{N}$ ([NNN], trans to eq $\mathrm{CH}_{3} \mathrm{CN}$ ) in cis$\left[\mathrm{Rh}_{2}(\mathrm{NNN})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}(\right.$ bpy $\left.)\right]\left[\mathrm{PF}_{6}\right]_{2}$. The eq $\mathrm{CH}_{3} \mathrm{CN}$ groups and the bridging ligands ([NNN] $]^{\circ}$ ) are twisted by $\sim 23.0^{\circ}$ and $\sim 20.3^{\circ}$, respectively, from the eclipsed configuration. cis $-\left[\mathbf{R h}_{2}(\mathbf{D T o l F})_{2}\left(\mathbf{C N C H}_{3}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$, (5). Compound 5 crystallizes in the space group Pbca. The cationic unit is shown in Figure 2.3. The coordination sphere of the $\mathrm{Rh}(\mathrm{II})$

Figure 2.2 Thermal ellipsoid plot for the cationic unit in $\mathbf{3}$ at the $50 \%$ probability level.

Figure 2.3 Thermal ellipsoid plot for the cationic unit in $\mathbf{5}$ at the 50\% probability level.
atoms is similar to those in $\mathbf{1 - 3}$, but with all the $\mathrm{CH}_{3} \mathrm{CN}$ ligands being substituted by $\mathrm{CH}_{3} \mathrm{NC}$. The Rh-Rh distance is $2.6262(4) \AA$, i.e., slightly longer than the corresponding distances in 1-3 and much shorter than in $\left[\mathrm{Rh}_{2}\left(p-\mathrm{CNC}_{6} \mathrm{H}_{4} \mathrm{CH}_{3}\right)_{8} \mathrm{I}_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}{ }^{95}$ and $\left[\mathrm{Rh}_{2}\left[\mathrm{CN}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{NC}_{4} \mathrm{Cl}_{2}\right] \mathrm{C1}_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}^{89}\right.$, for which the $\mathrm{Rh}-\mathrm{Rh}$ distances are 2.785(2) and 2.837(1) Å, respectively. The bond distances Rh-C (ax CH3NC) in 5 (2.099(2) and $2.080(2) \AA$ ) are longer than the corresponding distance in $\mathrm{Rh}_{2}(\mathrm{DPhF})_{4}\left(\mathrm{CNC}_{6} \mathrm{H}_{5}\right)^{82}$ (1.991(4) $\AA)$ and shorter than in $\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4} \cdot 2 \mathrm{CNC}_{6} \mathrm{H}_{4} \mathrm{R}\left\{\mathrm{R}=\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~N}, \mathrm{H}, \mathrm{CF}_{3}\right\}$ wherein the Rh-C (ax) distances are 2.148(4), 2.133(3), 2.122(3) $\AA,{ }^{133}$ respectively. The Rh-C (eq $\mathrm{CH}_{3} \mathrm{NC}$ ) distances are in the range 1.935(2)-1.949(2) $\AA$, and are comparable to the corresponding distances in $\left[\left\{\mathrm{Rh}_{2}(\mu-\mathrm{pz})_{2}(\mathrm{I})\left(\mathrm{CN}^{t} \mathrm{Bu}\right)_{4}\right\}_{2}(\eta-\mathrm{I})\right]\left[\mathrm{CF}_{3} \mathrm{SO}_{3}\right]$ \{Rh-C (eq $\left.\left.\mathrm{CN}^{t} \mathrm{Bu}\right) \sim 1.896(11)-1.958(12) \AA\right\} .{ }^{97}$ The Rh-N ([DTolF] ${ }^{-}$) bond distances range from $2.078(2)$ to $2.094(2) \AA$, and are thus longer than the corresponding ones in 1 . The dihedral angles C31-Rh1-Rh2-C33 and C35-Rh1-Rh2-C37 are 20.99(8) ${ }^{\circ}$ and 20.48(8) ${ }^{\circ}$, respectively. Additionally, the angles N1-Rh1-Rh2-N2 and N3-Rh1-Rh2-N4 are $17.79(6)^{\circ}$ and $17.97(6)^{\circ}$, respectively, following a similar trend as observed for 1-3.
cis- $\left[\mathbf{R h}_{\mathbf{2}}(\mathbf{F} \text {-form })_{\mathbf{2}}\left(\mathbf{C N C H}_{3}\right)_{6}\right]\left[\mathbf{B F}_{4}\right]_{2}$, (6). Compound $\mathbf{6}$ crystallizes in the same space group as 2, namely $P 2_{1} / \mathrm{c}$. The structure of the cationic unit in $\mathbf{6}$ is similar to 2 (Figure 2.4). The Rh-Rh bond distance is $2.6105(9) \AA$, which is $\sim 0.04 \AA$ longer than the corresponding distance in $\mathbf{2}$. The Rh-C (ax) bond distances are 2.074(4), 2.133(4) $\AA$, and the Rh-C(eq) bond distances are in the range 1.937(5)-1.953(4) $\AA$, which is similar to the range in 5. The Rh-N ([F-form] ${ }^{\text {) }}$ bond distances range from 2.079(3) to 2.098(3) $\AA$ and are longer than the corresponding distances in $\mathbf{2}$. The $\mathrm{CH}_{3} \mathrm{NC}$ groups and the bridging
[F-form] ligands are twisted from the eclipsed geometry by $21.6(2)^{\circ}, 23.5(2)^{\circ}$ and $18.1(1)^{\circ}, 17.2(1)^{\circ}$, respectively.
cis-[ $\left.\mathbf{R h}_{2}(\mathbf{N N N})_{2}\left(\mathbf{C N C H}_{3}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2},(7)$. As in the case of $\mathbf{3}$, complex 7 crystallizes in the space group Pbca. The thermal ellipsoid plot of the cationic unit is shown in Figure 2.5. The Rh-Rh bond distance is $2.5852(6) \AA$ which is $\sim 0.07 \AA$ longer than that in 3, following a similar trend as observed for $\mathbf{1} v s .5$ and $\mathbf{2} v s$. 6. The Rh-C (The Rh-C (ax $\mathrm{CH}_{3} \mathrm{NC} 2.089(4)$ and 2.093(4) $\AA$ ), and Rh-C (eq CH3 $\left.\mathrm{NC} 1.940(5)-1.950(5) \AA\right)$ are in a similar range as the corresponding distances in 5 and 6. The Rh-N $[\mathrm{NNN}]^{-}$bond distances range from $2.070(3)$ to $2.089(3) \AA$, which is $\sim 0.06 \AA$ longer than the corresponding Rh-N distances in $\mathbf{3}$. The four eq $\mathrm{CH}_{3} \mathrm{NC}$ ligands are twisted by 21.8(2) ${ }^{\circ}$ and $21.0(2)^{\circ}$ and the two [NNN] ligands by $18.9(1)^{\circ}$ and $19.8(1)^{\circ}$ from the eclipsed conformation.

Figure 2.4 Thermal ellipsoid plot for the cationic unit in 6 at the $50 \%$ probability level.

Figure 2.5 Thermal ellipsoid plot for the cationic unit in 7 at the $50 \%$ probability level.
cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathbf{P}\left(\mathbf{C}_{6} \mathbf{H}_{4}\right)\right]_{2}\left(\mathbf{C N C H}_{3}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$, (8). Compound $\mathbf{8}$ crystallizes in the centrosymmetric monoclinic space group $P 2{ }_{1} / \mathrm{c}$ with two independent dimetal complexes in one asymmetric unit and two isomers $8-R$ and $\mathbf{8}-S$, as was found for compound 4 . The cationic units of the two isomers $\mathbf{8}-R$ and $\mathbf{8}-S$ are shown in Figure 2.6. As is the case of $\mathbf{4}$, both the $R$ and $S$ isomers in $\mathbf{8}$ exhibit similar structural parameters. The Rh-Rh bond distances in $8-S$ and $8-R$ are 2.7682(6) and 2.766(1) $\AA$, respectively, i.e., longer than the corresponding distances in 4 (2.655(1) and 2.656(1) Å) and 5-7.

It is important to note that, to our initial surprise, $\mathbf{8}$ exhibits very similar distances for the ax and eq Rh-C bonds (with $\mathrm{CNCH}_{3}$ ) which is unprecedented for dirhodium compounds. The Rh-C (ax CH3NC) bond lengths are 2.023(4), 2.037(4) $\AA$ for 8 - $S$ and 2.033(3), 2.040(2) $\AA$ for 8-R, i.e., by $\sim 0.07 \AA$ shorter than the corresponding distances in 5-7. For both isomers of $\mathbf{8}$, the $\mathrm{Rh}-\mathrm{C}\left(\mathrm{eq} \mathrm{CH}_{3} \mathrm{NC}\right)$ distances are in the range 2.00-2.02
$\AA$. The Rh-P bond lengths for both isomers of $\mathbf{8}$ are $\sim 2.30 \AA$, i.e., by $\sim 0.10 \AA$ longer than the corresponding distances in cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\right] \cdot 2 \mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}$ and cis- $\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\right] \cdot 2 \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}^{134}$, and by $\sim 0.05 \AA$ longer than those in 4. ${ }^{105}$ The Rh-C (bridging phosphine) bond lengths in $\mathbf{8}$ are $\sim 2.07 \AA$, i.e., by $0.07 \AA$ longer than the corresponding distances in the orthometalated compounds cis$\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\right] \cdot 2 \mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}$, cis- $\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\right] \cdot 2 \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$ and 4. The $\mathrm{CH}_{3} \mathrm{NC}$ groups in $8-S$ are considerably twisted from an eclipsed conformation by $-35.9(1)^{\circ}$ and $-29.4(1)^{\circ}$, which are similar to the analogous ones for $\mathrm{CH}_{3} \mathrm{CN}$ in 4. The corresponding dihedral angles for the $\mathrm{CH}_{3} \mathrm{NC}$ groups in 8- $R$ are $30.7(1)^{\circ}$ and $31.8(1)^{\circ}$. Considerably smaller distortions are found for the bridging phosphine groups, with dihedral angles -21.29(8) and $-20.47(8)^{\circ}$ in 8-S. Likewise, for 8-R, they are $21.08(8)^{\circ}$ and $21.19(8)^{\circ}$. These distortions are similar to those encountered in 4, but larger than the angles in cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\right] \cdot 2 \mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}$, wherein the acetate bridging groups are twisted by $\sim 12.22^{\circ}$ from the eclipsed conformation.

The detailed bond distances, and dihedral angles for complexes $\mathbf{2 , 3}$ and 5-8 are all complied in Table 2.2

Figure 2.6 Thermal ellipsoid plot for the cationic unit of $\mathbf{8}-\mathrm{R}, \mathbf{8}-\mathrm{S}$ at the $50 \%$ probability level.

## NMR spectroscopic studies

In the ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{2}$, the characteristic triplet resonance, attributed to the bridging head H atoms on the [F-form] ${ }^{-}$ligands, appears at 7.49 ppm (Figure 2.7a), with the coupling constant to the $\mathrm{Rh}(\mathrm{II})$ centers being 3 Hz , similar to that in $\mathbf{1}$. The multiplet at 7.05 ppm results from the protons on the phenyl ring of the $[F-f o r m]^{-}$ligands. The resonance at $\delta=2.53 \mathrm{ppm}$ corresponds to the protons of the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands but the ratio of the integration between this resonance and the one at $\delta=7.49 \mathrm{ppm}$ (bridging head H ) is less than 6 after the dissolution of $\mathbf{2}$ in $\mathrm{CD}_{3} \mathrm{CN}$ for only 10 min , indicating the fast exchange of eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands with the $\mathrm{CD}_{3} \mathrm{CN}$ solvent molecules (Figure 2.7a). The spectrum obtained after dissolving 2 in $\mathrm{CD}_{3} \mathrm{CN}$ for 6 hours shows the total disappearance of this resonance, confirming the fast exchange process of the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands. For compound $\mathbf{3}$, the multiplet at $\delta=7.11 \mathrm{ppm}$ corresponds to the H nucleus on the phenyl ring of the bridging [ NNN$]^{-}$ligands. The resonances at $\delta=2.52 \mathrm{ppm}$ and $\delta=$ 2.31 ppm is attributed to the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands and $-\mathrm{CH}_{3}$ groups on the [ NNN$]^{-}$ligands respectively. The ratio of the integration of those two resonances is less than 1 after 10 min dissolution, indicating the lability of the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands in the $\mathrm{CD}_{3} \mathrm{CN}$ solution, same as 2. This is also confirmed by the disappearance of the resonance at $\delta=2.52 \mathrm{ppm}$ after 24 h dissolution in the dark.

For compounds $\mathbf{5}$ and $\mathbf{6}$, the triplet of the bridge-head H nuclei appear at $\delta=7.87$ and $\delta=7.84 \mathrm{ppm}$ respectively, downfield shifted compared to those of $\mathbf{1}$ and $\mathbf{2}$ with the same coupling constant to the two $\mathrm{Rh}(\mathrm{II})$ centers. The singlets at $3.67,2.61 \mathrm{ppm}$ in 5, 3.68,

Figure 2.7 (a) ${ }^{1} \mathrm{H}$ NMR spectra change of compound 2 after dissolving in $\mathrm{CD}_{3} \mathrm{CN}$ for 6 $h(b){ }^{1} \mathrm{H}$ NMR spectrum of compound 5 after dissolution in $\mathrm{CD}_{3} \mathrm{CN}$ for 1 week.
2.74 ppm in $\mathbf{6}, 3.66,2.73 \mathrm{ppm}$ in 7 correspond to the eq $\mathrm{CH}_{3} \mathrm{NC}$ and ax $\mathrm{CH}_{3} \mathrm{NC}$ ligands with integration ratios of $2: 1$. No exchange of the $\mathrm{CH}_{3} \mathrm{NC}$ ligands with $\mathrm{CD}_{3} \mathrm{CN}$ in 5-7 (Figure 2.7 b for 5 ) for one week indicates the stronger interaction of those $\mathrm{CH}_{3} \mathrm{NC}$ with the dimetal core in those compounds.

The X-ray crystallographic data for the orthometalated compounds $\mathbf{4}$ and $\mathbf{8}$ revealed racemic mixtures of the $R$ and $S$ isomers; the Rh centers are supported by two cis $\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]^{-}$groups in a head-to-tail orientation. As evidenced by the ${ }^{1} \mathrm{H}$-NMR spectra, both isomers exhibit the same chemical shifts due to fast rotation of the molecules in solution. The presence of only one resonance for $\mathrm{CH}_{3} \mathrm{CN}$ in the ${ }^{1} \mathrm{H}$ NMR spectrum of 4 , within 10 min of dissolution, indicates fast exchange of the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands with the $\mathrm{CD}_{3} \mathrm{CN}$ solvent due to the strong $\sigma$-donating ability of the bridging phosphine ligands. In contrast, due to the decreased lability of $\mathrm{CH}_{3} \mathrm{NC}$, as compared to $\mathrm{CH}_{3} \mathrm{CN}$, and the asymmetry of the bridging ligands, the ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{8}$ displays three $\mathrm{CH}_{3} \mathrm{NC}$ resonances at $\delta 3.48,3.27$ and 2.50 ppm , in a 1:1:1 ratio (Figure 2.8a), which correspond to eq $\mathrm{CH}_{3} \mathrm{NC}$ trans to the P and C atoms as well as the ax $\mathrm{CH}_{3} \mathrm{NC}$ groups, respectively. A monitoring of $\mathbf{8}$ with ${ }^{1} \mathrm{H}$ NMR spectroscopy in $\mathrm{CD}_{3} \mathrm{CN}$, however, revealed slow decomposition as indicated by the disappearance of the three aforementioned $\mathrm{CH}_{3} \mathrm{NC}$ resonances at the same rate and the concomitant appearance of a new resonance at $\delta 3.38$ ppm in the ${ }^{1} \mathrm{H}$ NMR spectra (Figure 2.8a). The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of $\mathbf{8}$ exhibits a doublet at $\delta \sim 21 \mathrm{ppm}\left({ }^{1} \mathrm{~J}_{\mathrm{Rh}-\mathrm{P}}=101.5 \mathrm{~Hz}\right)$ with the characteristic ${ }^{102} \mathrm{Rh}-{ }^{31} \mathrm{P}$ coupling; ${ }^{135}$ the doublet decreases in intensity and after 12 h , new resonances appear in the spectrum, and increase in intensity with time (Figure 2.8 b ; spectra at 12 h and 4 days). The

instability of $\mathbf{8}$ in solution as a function of time, indicated by the NMR data, is also corroborated by the fragmentation pattern of $\mathbf{8}$ in the MS studies. On the contrary, the ESI-MS data for 2-7 show the main peaks corresponding to the parent species with a $2^{+}$ charge and the appropriate isotopic distributions. Sequential loss of the monodentate ligands, either $\mathrm{CH}_{3} \mathrm{CN}$ or $\mathrm{CH}_{3} \mathrm{NC}$, is observed in the ESI-MS of 2-7.

In the ESI-MS spectra of $\mathbf{2 - 3}, \mathbf{5 - 7}$, all the main peaks are correspondent to the $2^{+}$ charge with the appropriate isotope distributions, assigned to be the cationic part of the compounds respectively. Moreover, sequential loss of the monodentate ligands, either $\mathrm{CH}_{3} \mathrm{CN}$ or $\mathrm{CH}_{3} \mathrm{NC}$, are observed in the ESI-MS spectra of those compounds. In the ESI spectrum of $\mathbf{8}$ in $\mathrm{CH}_{3} \mathrm{CN}$, different small fragments of the molecule are observed, with the assignments as follows: $\left[\mathrm{Rh}_{2}\left\{\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\right]^{2+}$, 366.00; $\left[\mathrm{Rh}_{2}\left\{\mathrm{Ph}_{2} \mathrm{P}\right.\right.$ $\left.\left.\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\left(\mathrm{CNCH}_{3}\right)\right]^{2+}, \quad 384.51 ; \quad\left[\mathrm{Rh}_{2}\left\{\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\left(\mathrm{CNCH}_{3}\right)_{2}\right]^{2+}$, 405.00; $\left[\mathrm{Rh}_{2}\left\{\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\left(\mathrm{CNCH}_{3}\right)_{3}\right]^{2+}, \quad 425.51 ; \quad\left[\mathrm{Rh}_{2}\left\{\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\left(\mathrm{CNCH}_{3}\right)_{4}\right]^{2+}, \quad 446.03$; $\left[\mathrm{Rh}_{2}\left\{\mathrm{Ph}_{2} \quad \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\left(\mathrm{CNCH}_{3}\right)_{5}\right]^{2+}, \quad 466.56 ; \quad\left[\mathrm{Rh}\left\{\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\right]+\mathrm{H}^{+}, \quad$ 625.07; $\left[\operatorname{Rh}\left\{\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\left(\mathrm{CNCH}_{3}\right)\right]+\mathrm{H}^{+}, \quad 666.09 ; \quad\left[\operatorname{Rh}\left\{\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\left(\mathrm{CNCH}_{3}\right)_{2}\right]+\mathrm{H}^{+}, \quad 707.13 ;$ $\left[\mathrm{Rh}_{2}\left\{\mathrm{PPh}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\left(\mathrm{CNCH}_{3}\right)_{3}\right]\left(\mathrm{BF}_{4}\right)^{+}, \quad 938.08 ; \quad\left[\mathrm{Rh}_{2}\left\{\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\left(\mathrm{CNCH}_{3}\right)_{4}\right]\left(\mathrm{BF}_{4}\right)^{+}$, 979.11; $\left[\mathrm{Rh}_{2}\left\{\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\left(\mathrm{CNCH}_{3}\right)_{5}\right]\left(\mathrm{BF}_{4}\right)^{+}$, 1020.13; $\left[\mathrm{Rh}_{2}\left\{\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right\}_{2}\left(\mathrm{CNCH}_{3}\right)_{6}\right]\left(\mathrm{BF}_{4}\right)^{+}$, 1061.16. These data reveal the instability of the compound, in accord with the NMR studies. The identity of the decomposition product has not been determined as of yet, but it is postulated to be the product caused by the cleavage of the Rh-Rh bond.

## Electronic absorption spectral studies

The electronic absorption data for $\mathbf{1 - 8}$ measured in $\mathrm{CH}_{3} \mathrm{CN}$ are summarized in Table 2.3 and selected spectra in the range $200-600 \mathrm{~nm}$ are depicted in Figure 2.9.

Given that compounds $\mathbf{1 , 2}$ and 5, $\mathbf{6}$ are structurally analogous, it is not surprising that similar electronic absorption features are observed in each case. Compounds 1-2 (Figure 2.9a) and 5-6 exhibit characteristic intense bands at $\lambda \sim 260 \mathrm{~nm}$, which are ascribed to metal-centered transitions involving contributions from the orbitals of both the bridging and monodentate ligands. In $\mathbf{1 - 3}$ (Figure $2.9 \mathrm{a}, \mathrm{c}$ ), there is a shoulder of moderate intensity at $\lambda \sim 320 \mathrm{~nm}\left(\varepsilon \sim 8.0 \times 10^{3} \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ in addition to the intense absorption at $\lambda$ $=258 \mathrm{~nm}$ (Figure 2.9a, c). It is notable that two weak but obvious shoulders appear at $\lambda$ $=420$ and $515 \mathrm{~nm}\left(\varepsilon \sim 10^{3}\right.$ and $500 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$, respectively); these maxima display significant hypsochromic shifts as compared to the lowest energy bands of the series $\mathrm{Rh}_{2}(\mathrm{R}-\mathrm{DPhF})_{4}\left(\mathrm{R}=\mathrm{OCH}_{3}, \mathrm{Cl}\right)$, which occur at $\lambda>800 \mathrm{~nm}$ and are attributed to the $\mathrm{Rh}_{2}\left(\pi^{*}\right) \rightarrow \mathrm{Rh}_{2}\left(\sigma^{*}\right)$ transitions. ${ }^{136,137}$ The aforementioned band shifts indicates the differences in the electronic structures of the partial paddlewheel $\mathrm{Rh}_{2}(\mathrm{II}, \mathrm{II})$ compounds 1-3 after substituting two cis-formamidinate bridging ligands with four monodentate $\mathrm{CH}_{3} \mathrm{CN}$ groups. Furthermore, the substitution of $\mathrm{CH}_{3} \mathrm{CN}$ with $\mathrm{CH}_{3} \mathrm{NC}$ in the series 5-7 results in a shift of the lowest energy bands to higher energies ( $\lambda \sim 420 \mathrm{~nm}$ ) with no apparent absorptions at $\lambda>500 \mathrm{~nm}$ (Figure 2.9b, c). The electronic absorption spectrum of $\mathbf{3}$ is similar to those of $\mathbf{1}$ and $\mathbf{2}$, presumably due to the similarity of the interactions between $\mathrm{Rh}_{2}$ (II,II) with the $[\mathrm{NNN}]^{-}$and $\left[\mathrm{DTolF}^{-}\right.$bridging ligands. The intense absorption maximum at $\lambda=250 \mathrm{~nm}$ is of the same character as that in $\mathbf{1}$ and $\mathbf{2}$ at $\sim 260$

Table 2.3 Electronic absorption data for compounds 1-8 in $\mathrm{CH}_{3} \mathrm{CN}$.

| Compound | $\lambda_{\max }\left(\varepsilon \times 10^{3}\right)\left(\mathrm{nm}, \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ |
| :---: | :---: |
| $\mathbf{1}$ | $258(55), \sim 321(8.8), \sim 425(1.05), \sim 521(0.45)$ |
| $\mathbf{2}$ | $254(47.5), \sim 312(7.4), \sim 416(0.85), \sim 510(0.4)$ |
| $\mathbf{3}$ | $244(19.28), 285(13.9), \sim 463(0.8), \sim 534(0.2)$ |
| $\mathbf{4}$ | $206(67), \sim 246(23), 286(19.3), \sim 355(1.5), 478(0.57)$ |
| $\mathbf{5}$ | $267(46.6), \sim 313(10.9), \sim 345(5), \sim 392(1.2), \sim 425(0.76)$ |

| $\mathbf{8}$ | $204(120), 273(14), \sim 290(11), 362(10)$ |

Figure 2.9 Overlay of the electronic spectra for (a) $\mathbf{1}$ and 2, (b) $\mathbf{1}$ and 5, (c) $\mathbf{3}$ and 7, and (d) 4 and 8 .
nm , whereas the transition at $\lambda=285 \mathrm{~nm}$ is tentatively assigned to the intramolecular ${ }^{1} \pi \pi^{*}$ transition of the [NNN] ligands in $\mathbf{3}$ because it is also present, albeit slightly shifted, in the electronic spectrum of the free ligand as well as 7. A distinct feature in the electronic spectrum of $\mathbf{4}$ is the weak but apparent absorption at $\lambda=478 \mathrm{~nm}\left(\varepsilon \sim 570 \mathrm{M}^{-}\right.$ ${ }^{1} \mathrm{~cm}^{-1}$ ) as opposed to $\mathbf{8}$, which exhibits a moderately strong absorption at $\lambda=362 \mathrm{~nm}(\varepsilon \sim$ $9700 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ ) (Figure 2.9d). This difference in the spectra of $\mathbf{4}$ and $\mathbf{8}$ reflects the drastic changes in their electronic configurations upon substitution of $\mathrm{CH}_{3} \mathrm{CN}$ for $\mathrm{CH}_{3} \mathrm{NC}$ ligands.

## Computational studies

DFT calculations were performed on the cationic units of $\mathbf{1 - 8}$ in an attempt to gain further insight into their structural, electrochemical and electronic absorption properties. The structural parameters of the optimized metal complexes closely resemble those experimentally found by X-ray crystallography. In 1-3, the Rh-Rh bond distances in the cationic units are $\sim 0.09 \AA$ shorter than the distances in 5-7. Moreover, a significant decrease of the $\mathrm{Rh}-\mathrm{L}$ bond distances ( L monodentate ligand, $\mathrm{L}: \mathrm{CH}_{3} \mathrm{CN}$ in 1-3, L : $\mathrm{CH}_{3} \mathrm{NC}$ in 5-7) was also successfully predicted by the calculations for the pairs $\mathbf{1 / 5}, \mathbf{2} / \mathbf{6}$, $3 / 7$. The $\mathrm{Rh}-\mathrm{Rh}$ bond distance in the optimized cationic unit of $\mathbf{4}$ is comparable to the crystal structure, whereas in $\mathbf{8}$, it is $\sim 0.05 \AA$ longer than the experimentally value. In $\mathbf{4}$, slightly longer Rh-N bond distances (eq $\mathrm{CH}_{3} \mathrm{CN}$, trans to C ) than the $\mathrm{Rh}-\mathrm{N}$ bond distances (eq $\mathrm{CH}_{3} \mathrm{CN}$ trans to P ) were also successfully predicted, indicating the stronger trans influence imposed by the Rh-C bond. For 8, the Rh-C (ax $\mathrm{CNCH}_{3}$ ) and Rh-C (eq $\mathrm{CNCH}_{3}$ ) bond distances are very similar, in agreement with the X-ray diffraction data.

The calculated dihedral angles $\omega$ in $\mathbf{1 - 8}$, defined by the eq ligands and the two Rh centers, are slightly higher than those in the crystal structures but within a similar range. In general, the good agreement of the bond distances and angles with the X-ray data indicates that the level of theory and the basis sets that were used are reliable.

DFT calculations for $\mathrm{CH}_{3} \mathrm{CN}$ and $\mathrm{CH}_{3} \mathrm{NC}$ were also conducted to illustrate the different electronic properties of the ligands. From the MO diagrams depicted in Figure 2.10, the HOMO of $\mathrm{CH}_{3} \mathrm{NC}$ between the C and N atoms has $\sigma^{*}$ character with the electron density mainly localized on the terminal C atom, whereas the HOMO of $\mathrm{CH}_{3} \mathrm{CN}$ is mainly the $\pi$ bonding orbital between the C and N atoms. Moreover, the HOMO of $\mathrm{CH}_{3} \mathrm{NC}$ lies higher than that of $\mathrm{CH}_{3} \mathrm{CN}$ (the HOMO and HOMO-1 for $\mathrm{CH}_{3} \mathrm{CN}$ are degenerate). These features explain the better $\sigma$-donating ability of $\mathrm{CH}_{3} \mathrm{NC}$ as compared to $\mathrm{CH}_{3} \mathrm{CN}$. The LUMO+1 and LUMO+2 levels for both ligands are sets of degenerate $\pi^{*}$ orbitals, lying at $\sim 0.12 \mathrm{eV}$ and $\sim 0.56 \mathrm{eV}$ for $\mathrm{CH}_{3} \mathrm{NC}$ and $\mathrm{CH}_{3} \mathrm{CN}$, respectively, in accord with the improved $\pi$-accepting ability of $\mathrm{CH}_{3} \mathrm{NC}$. The aforementioned factors also affect the Rh-Rh bond lengths of compounds 5-8 in an interdependent fashion (vide infra).

Figure 2.10 MO diagrams for the ligands $\mathrm{CH}_{3} \mathrm{CN}$ and $\mathrm{CH}_{3} \mathrm{NC}$ with graphical representations of the HOMO, LUMO+1, LUMO+2 (iso-value 0.04); the HOMO and HOMO-1 for $\mathrm{CH}_{3} \mathrm{CN}$ are degenerate.

## Bonding in the dirhodium unit

It is widely accepted that without perturbation from the ligand field, the electronic configuration of the $\mathrm{Rh}_{2}$ (II,II) dimetallic core is $\sigma^{2} \pi^{4} \delta^{2} \delta^{* 2} \pi^{* 4} \sigma^{* 0}$, resulting in a bond order of one. ${ }^{21}$ Upon coordination of the four [DTolF] ${ }^{-}$ligands, however, the dirhodium unit adopts the electronic configuration $\sigma^{2} \pi^{4} \delta^{2} \pi^{* 4} \delta^{* 2} \pi^{* 0}$ as the $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ orbital is destabilized due to the antibonding interaction with the $\mathrm{p} \pi$ lone pairs of the bridging [DTolF] ${ }^{-}$groups. ${ }^{136}$ It is notable that in the two sets of dirhodium compounds $\mathbf{1 , 2}$ and $\mathbf{5}$, 6 with monodentate acetonitrile and methyl isocyanide ligands, respectively, however, unusual configurations of the molecular orbitals arise; these differences entail lowering of the $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ below the $\mathrm{Rh}_{2}(\delta)$ and considerable elevation of the $\mathrm{Rh}_{2}(\sigma)$ orbitals (for
example, $\operatorname{Rh}_{2}(\delta)$ lies $\sim 0.98$ and 1.02 eV higher in energy as compared to $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ in $\mathbf{1}$ and 2, respectively; Table 2.4, Figure 2.11 for $\mathbf{1}$ and 5; Table 2.5, Figure 2.12 for $\mathbf{2}$ and 6). The substitution of two cis-[DTolF] by four eq $\mathrm{CH}_{3} \mathrm{CN}$ in $\mathrm{Rh}_{2}(\mathrm{DTolF})_{4}$ and the presence of two ax $\mathrm{CH}_{3} \mathrm{CN}$ ligands lead to stabilization of the $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ as compared to $\operatorname{Rh}_{2}(\delta)$ in $\mathbf{1}$. This is attributed to the combined effects of two factors: the presence of only two bridging ligands in 1 induces a staggered configuration with $\omega \sim 20^{\circ}$ and a subsequent reduced overlap between the two $\mathrm{d}_{\mathrm{xy}}$ orbitals of the two Rh (II) centers, which are responsible for the formation of the $\mathrm{Rh}_{2}(\delta)$ and $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ bonds. Furthermore, there are interactions of the $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ with the low lying $\pi^{*}$ orbitals of the eq monodentate $\mathrm{CH}_{3} \mathrm{CN}$ ligands as well as the $\mathrm{p} \pi$ lone pairs of the formamidinate groups which further stabilize the $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ (Figure 2.13) and slightly destabilize the $\mathrm{p} \pi$ lone pair, thus rendering it the HOMO in $\mathbf{1}$ (it has $27 \% \mathrm{Rh}_{2}\left(\delta^{*}\right)$ and $71 \%[\mathrm{DTolF}]^{-}$contributions; Table 2.4).

In contrast to $\mathbf{1}$ and $\mathbf{2}$, the $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ orbital in $\mathbf{3}$ is slightly higher in energy as compared to $\mathrm{Rh}_{2}(\delta)$ (Table 2.6), which is not surprising as the graphic representation of its $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ indicates negligible participation of the low-lying $\pi^{*}$ orbitals of the $\mathrm{CH}_{3} \mathrm{CN}$ ligands. For similar reasons (Figure 2.13), the $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ orbitals are lower in energy as compared to $\mathrm{Rh}_{2}(\delta)$ in 5-7. Both orbitals $\mathrm{Rh}_{2}(\pi)$ and $\mathrm{Rh}_{2}\left(\pi^{*}\right)$, however, are stabilized as compared to their anologs $\mathbf{1 - 3}$, since their interactions with the low lying empty $\pi^{*}$ orbitals of the $\mathrm{CH}_{3} \mathrm{NC}$ ligands are stronger due to the better $\pi$-accepting ability of $\mathrm{CH}_{3} \mathrm{NC}$.

Figure 2.11 MO diagrams involving the $\mathrm{Rh}_{2}$ (II,II) units in $\mathbf{1}$ and $\mathbf{5}$ obtained by DFT calculations (iso-value $=0.04$ ).

Figure 2.12 MO diagrams involving the $\mathrm{Rh}_{2}$ (II,II) units in 2 and $\mathbf{6}$ obtained by DFT calculations (iso-value $=0.04$ ).

Figure 2.13 Representation of the orbital interactions between $\mathrm{Rh}_{2}\left(\delta^{*}\right)$, $\mathrm{p} \pi$ lone pairs on the bridging ligand and the low lying $\pi^{*}$ orbital on the $\mathrm{CH}_{3} \mathrm{NC}$ ligands.

Apart from the $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ orbital becoming stabilized due to its interactions with two staggered [DTolF] ligands in $\mathbf{1}$, the $\mathrm{Rh}_{2}(\sigma)$ orbital increases in energy as compared to the $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ orbital (Figure 2.11 , Table 2.4) due to the interactions with the two ax $\mathrm{CH}_{3} \mathrm{CN}$ ligands present in $\mathbf{1}$ but not in $\mathrm{Rh}_{2}(\mathrm{DTolF})_{4}$. Analogous observations were made for the orbital levels in 2 and 3 (Figure 2.12, Table 2.5 for 2, Table 2.6 for 3). Importantly, the increase in energy for the $\mathrm{Rh}_{2}(\sigma)$ and $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbitals for the methyl isocyanide analogs 5-7 (Figures 2.11 and 2.12, Tables 2.4 and 2.5 for $\mathbf{5}$ and 6, Table 2.6 for 7 ) is even more pronounced as compared to $\mathbf{1 - 3}$ due to the better $\sigma$-donating ability of $\mathrm{CH}_{3} \mathrm{NC}$. Additionally in 5-7, the $\mathrm{Rh}_{2}(\pi), \mathrm{Rh}_{2}\left(\pi^{*}\right)$ and $\mathrm{Rh}_{2}(\delta), \mathrm{Rh}_{2}\left(\delta^{*}\right)$ orbitals are
stabilized by 0.2 to 0.8 eV as compared to $\mathbf{1 - 3}$, respectively. This is attributed to the increased $\pi$-accepting ability of $\mathrm{CH}_{3} \mathrm{NC}$ (vide supra) as the $\mathrm{Rh}_{2}(\pi), \mathrm{Rh}_{2}\left(\pi^{*}\right)$ orbitals have significant contributions from both the ax and eq $\mathrm{CH}_{3} \mathrm{NC}$ ligands and the $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ orbital has $\sim 20 \%$ contribution from the eq $\mathrm{CH}_{3} \mathrm{NC}$ ligands (Table 2.4), e.g., the energy difference between the $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ and $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbitals is $\sim 1.32$ and $\sim 0.05 \mathrm{eV}$ in 5 and $\mathbf{1}$, respectively (Figure 2.12 and Table 2.5 for compounds $\mathbf{2}$ and $\mathbf{6}$ ).

In 8, the MOs pertaining to $\mathrm{Rh}_{2}($ II, II), which are primarily metal-based orbitals (Table 2.7), are in the order of $\pi^{4} \delta^{2} \delta^{*^{2}} \pi^{*^{4}} \sigma^{2} \sigma^{* 0}$ (Figure 2.14). The stabilization of the $\pi$ symmetry orbitals is attributed to significant $\pi$-backbonding from the dirhodium unit to the $\mathrm{CH}_{3} \mathrm{NC}$ ligands, as in compounds $\mathbf{5 - 7}$. In the case of $\mathbf{8}$, however, the much stronger interactions of the dirhodium core with the ax $\mathrm{CH}_{3} \mathrm{NC}$ ligands lead to a significant increase in the energy of the $\mathrm{Rh}_{2}(\sigma)$ orbital to the extent that it actually becomes the HOMO level. As indicated from the MO diagram for 8 (Figure 2.14), the energy difference between the $\mathrm{Rh}_{2}(\sigma)$ and $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ orbitals is 1.66 eV , i.e., $\sim 0.32 \mathrm{eV}$ higher than that for $\mathbf{5}$ (Table 2.4). In contrast to $\mathbf{5}$, the $\mathrm{Rh}_{2}(\delta)$ and $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ orbitals in $\mathbf{8}$ are very close in energy as larger distortions from the eclipsed configuration occur for the $\mathrm{CH}_{3} \mathrm{NC}$ (the groups are twisted by $\omega \sim 30^{\circ}$ ); this situation results in decreased orbital overlap which reduces the energy difference between the $\mathrm{Rh}_{2}(\delta)$ and $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ orbitals. The graphical representation also indicates that both $\mathrm{Rh}_{2}(\delta)$ and $\mathrm{Rh}_{2}\left(\delta^{*}\right)$ orbitals have similar and strong interactions with the eq $\mathrm{CH}_{3} \mathrm{NC}$ ligands (Figure 2.14).

## TD-DFT calculations

The calculated and experimental electronic absorption spectra for 1-4, 5-8 are overlaid in Figures 2.15 and 2.16. The similarities between the spectra confirm the reliability of the calculations. The compositions of selected frontier MOs of the calculated cationic units for 1-8 are listed in Table 2.8.

The orbital compositions for HOMO-2 to LUMO+2, which were found to be mainly involved in the electronic transitions derived from the TD-DFT/PCM calculations for 18, are listed in Table 2.8 and the spatial plots for $\mathbf{1 - 4}, \mathbf{5 - 8}$ are displayed in Figures 2.17 and 2.18. The unoccupied orbitals for compounds $\mathbf{1}, \mathbf{2}, \mathbf{5}$ and $\mathbf{6}$ exhibit similar character, namely the LUMOs $\operatorname{Rh}_{2}\left(\sigma^{*}\right)$ are primarily rhodium based orbitals ( $\sim 65 \%$ ) with $\sim 15 \%$ contribution from the ax ligands $\left(\mathrm{CH}_{3} \mathrm{CN}\right.$ for $\mathbf{1 , 2}$ and $\mathrm{CH}_{3} \mathrm{NC}$ for $\mathbf{5}, \mathbf{6}$; Table 2.8). The other two low-lying orbitals, i.e., the LUMO +1 ( $\sigma^{*}{ }_{\text {L-Rh-DToIF }}$ ) and LUMO $+2\left(\sigma^{*}\right.$ L-Rh-DToIF $)$, have $45 \% \mathrm{Rh}, 35 \%$ bridging ligand ([DTolF] for $\mathbf{1 , 5} 5$ and $[\mathrm{F}-\text { form }]^{-}$for 2, 6) and $20 \% \mathrm{eq}$ monodentate ligand $\left(\mathrm{CH}_{3} \mathrm{CN}\right.$ in $\mathbf{1 , 2}$ and $\mathrm{CH}_{3} \mathrm{NC}$ in $\mathbf{5 , 6}$ ) contributions.

Variable contributions were obtained, however, for the occupied orbitals of $\mathbf{1 , 2}$ and 5, 6. For 1, the formamidinate orbitals mainly contribute to the HOMO-2 $\left(\pi^{*}{ }_{\text {phenyl }}\right)$, HOMO-1 ( $\mathrm{p} \pi_{\mathrm{DTolF}}$ ) and HOMO ( $\pi^{*}{ }_{\text {Rh-DTolF }}$ ) (Figure 2.17, Table 2.8). Similar orbital characters are encountered in $\mathbf{2}$. As discussed earlier, however, the HOMO-2 in $\mathbf{5}$ and $\mathbf{6}$ have $\mathrm{Rh}_{2}(\sigma)$ character, whereas the HOMO-1 ( $\mathrm{p} \pi_{\text {bridging }}$ ) and HOMO ( $\mathrm{p} \pi_{\text {bridging }}$ ) comprise a set of closely lying orbitals with $\mathrm{p} \pi$ lone-pair character from the bridging formamidinate ligands and much smaller contributions from metal-based orbitals (ratio ~5:1) (Figure 2.18, Table 2.8). For 3 and 7, which are supported by triazenide bridging

groups, the electronic transitions mainly involve the orbitals from HOMO-2 to LUMO+2. These orbitals in $\mathbf{3}$ and 7 exhibit very similar characters to the corresponding orbitals in 1 and 5, respectively.

For 4 and 8, the spatial plots of the LUMOs indicate that they are also of $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ character but with slightly lower Rh orbital contributions (50\%) as compared to 1-3 and 5-7. The two low-lying unoccupied orbitals LUMO +1 and LUMO +2 in 4 are composed of $\sim 60 / 40 \%$ bridging ligand/metal characters. A similar composition is also found for the LUMO+1 in 8, whereas the LUMO+2 has $\sim 50 / 50 \%$ bridging ligand/metal based characters. For the occupied orbitals, the HOMOs of both compounds are mainly metal-
based, but their spatial plots reveal $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ and $\mathrm{Rh}_{2}(\sigma)$ characters in 4 and $\mathbf{8}$, respectively (Figures 2.17 and 2.18 ). The HOMO-1 ( $\left.\pi^{*}{ }_{\text {phenyl }}\right)$ and HOMO-2 $\left(\pi^{*}{ }_{\text {pheny }}\right)$ in $\mathbf{8}$ comprise a set of closely lying orbitals residing on the two bridging ligands; in contrast, both orbitals in 4 have $\sim 40 \%$ metal character. Other orbitals with dirhodium character, which are involved in the excited states of $\mathbf{4}$, derived from TD-DFT calculations, include the HOMO-18 to HOMO-14 and HOMO-5 to HOMO-3 (vide infra). A notable point, however, is that most of these orbitals also have significant contributions from bridging ligands with several of them having equal or even higher bridging ligand components, thus no $\mathrm{Rh}_{2}(\sigma, \pi, \delta)$ character can be assigned to them.

The different substituents on the formamidinate ligands affect the energy differences between the orbitals of $\mathbf{1 , 2}$ and $\mathbf{5}, \mathbf{6}$. As shown in the MO diagrams (Figure 2.19), the orbitals in $\mathbf{2}$ and $\mathbf{6}$ lie at lower energies than in $\mathbf{1}$ and 5, respectively, but the energy differences between the orbital sets are different for each compound. For example, the energies of the HOMO ( -5.91 eV ) and LUMO $(-2.16 \mathrm{eV})$ for $\mathbf{2}$ are by $\sim 0.16$ and 0.05 eV lower than the corresponding orbital energies for 1 due to the electron withdrawing fluorine groups on the bridging formamidinate ligands in 2. Furthermore, the various contributions from the bridging ligands result in different degrees of stabilization for the different orbitals in $\mathbf{1}$ and $\mathbf{2}$. As shown in Table 2.8, the bridging ligands have major contributions to the HOMOs but with only minor participation in the LUMOs. Similar trends are also observed for $\mathbf{5}$ and $\mathbf{6}$. On the other hand, the HOMOs of $\mathbf{5}$ and $\mathbf{6}$ are stabilized as compared to their $\mathrm{CH}_{3} \mathrm{CN}$ congeners $\mathbf{1}$ and 2, due to their antibonding character in $\mathbf{1}$ and $\mathbf{2}$, as opposed to their non-bonding nature in $\mathbf{5}$ and $\mathbf{6}$. Furthermore, the

LUMOs $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ for $\mathbf{5}, \mathbf{6}$ become destabilized, as compared to $\mathbf{1}$ and $\mathbf{2}$, due to the better $\sigma$-donating ability of the ax $\mathrm{CH}_{3} \mathrm{NC}$ ligands, which essentially leads to larger HOMOLUMO energy gaps in $\mathbf{5}$ and $\mathbf{6}$ vs. $\mathbf{1}$ and 2, respectively (Figure 2.19). Similarly, in 7, the HOMO is stabilized by $\sim 0.27 \mathrm{eV}$, whereas the LUMO is destabilized by $\sim 0.26 \mathrm{eV}$, as compared to the corresponding orbitals in $\mathbf{3}$, for the same reason that accounts for the larger HOMO-LUMO energy gap in $\mathbf{5}$ as compared to $\mathbf{1}$. In compound $\mathbf{4}$, the HOMO and LUMO lie at -6.42 and -1.92 eV respectively, i.e., they are by $\sim 0.25 \mathrm{eV}$ lower than the corresponding orbitals in $\mathbf{8}$. The destabilization of the $\mathrm{Rh}_{2}(\sigma)(\mathrm{HOMO})$ and $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$

Figure 2.19 Energy levels of the MOs for 1-8 derived from TD-DFT calculations.
(LUMO) in $\mathbf{8}$ are attributed to the better $\sigma$-donating ability of the ax $\mathrm{CH}_{3} \mathrm{NC}$. The destabilization of the $\mathrm{HOMO}_{\mathrm{Rh}_{2}}(\sigma)$ thus results in a weaker $\mathrm{Rh}-\mathrm{Rh}$ bond in 8.

The electronic transitions for $\mathbf{1}$ and 2 computed by TD-DFT calculations are summarized in Table 2.9. As the results of the TD-DFT calculation with the solvation model indicate, the lowest energy band in $\mathbf{1}$ involves a HOMO $\rightarrow$ LUMO transition occurring at $538 \mathrm{~nm}(f=0.0015)$, thus it is primarily a ligand-to-metal charge-transfer transition (LMCT) with minor $\operatorname{Rh}_{2}\left(\delta^{*}\right) \rightarrow \operatorname{Rh}_{2}\left(\sigma^{*}\right)$ character (Tables 2.4 and 2.8). The corresponding transition in $\mathbf{2}$ occurs at $525 \mathrm{~nm}(f=0.0011)$ and exhibits a hypsochromic shift as compared to $\mathbf{1}$, which is attributed to the larger HOMO-LUMO energy gap in $\mathbf{2}$ due to the reasons we noted in the aforementioned section. The next higher energy absorption bands in 1 and 2 are in the range 435-440 nm (Table 2.9), involving transitions from HOMO-5 and HOMO-6 to LUMO in 1 and HOMO-5, HOMO-4 to LUMO in 2. As indicated in Table 2.9, these occupied orbitals have significant $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ contribution, thus attributing metal-centered character (MC) to these transitions. The excited states 4-7 in $\mathbf{1}$ and $\mathbf{2}$ involve transitions from HOMO, HOMO-1 to LUMO+1 and LUMO+2, and occur in the broad range $330-410 \mathrm{~nm}$. The involvement of HOMO and HOMO-1 orbitals leads to a bathochromic shift in $\mathbf{1}$ as compared to $\mathbf{2}$ (Table 2.9). The next set of transitions in the range 300-320 nm originates primarily from HOMO-15, HOMO-14, HOMO-13 to LUMO in both 1 and 2. Since the three occupied orbitals mainly consist of $\mathrm{Rh}_{2}(\pi)$ and $\mathrm{Rh}_{2}(\sigma)$ related orbitals (vide supra), the transitions are considered MC with moderate oscillator factors due to being allowed by the Laporte rules.

Table 2.9 Excited states calculated by TD-DFT/PCM $\left(\mathrm{CH}_{3} \mathrm{CN}\right.$ as the solvent) with major transitions* involved in the excitations, transition coefficients, vertical excitation energies (nm), and oscillator strengths ( $f$ ) for $\mathbf{1}$ and $\mathbf{2}$.

* $2 \mid$ coefficient $\left.\right|^{2}>0.2$

For the isocyanide analogs 5 and $\mathbf{6}$, the first two excited states are mainly HOMO, HOMO-1 to LUMO (LMCT) transitions (Table 2.10) which occur at $413 \mathrm{~nm}(f=$ $0.0016)$ and $392 \mathrm{~nm}(f=0.0154)$ for 5 and $409 \mathrm{~nm}(f=0.0011)$ and $387 \mathrm{~nm}(f=0.0167)$ for 6. The participation of HOMO and HOMO-1 orbitals leads to slight hypsochromic shifts from 5 to $\mathbf{6}$, in agreement with the more stabilized HOMO in $\mathbf{6}$. Furthermore, their hypsochromic shifts, as compared to the $\mathrm{CH}_{3} \mathrm{CN}$ analogs $\mathbf{1}$ and 2, are attributed to the larger HOMO-LUMO energy gaps in 5, 6. The next series of bands involve HOMO, HOMO-1 to LUMO+1 and LUMO+2 transitions in the absorption region 320-350 nm.

Similar bathochromic shifts from $\mathbf{6}$ to $\mathbf{5}$ are observed for these transitions due to the involvement of the HOMO and HOMO-1 orbitals. The excited states 7-10, in the range 295 to 300 nm , correspond to transitions from $\mathrm{Rh}_{2}\left(\pi^{*}\right), \mathrm{Rh}_{2}(\sigma)$ to $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbitals (MC), which renders them insensitive to the bridging ligand identity and thus gives rise to the same energies for both 5 and 6 (Table 2.10).

Table 2.10 Excited states calculated by TD-DFT/PCM $\left(\mathrm{CH}_{3} \mathrm{CN}\right.$ as the solvent) with major transitions* involved in the excitations, transition coefficients, vertical excitation energies (nm), and oscillator strengths ( $f$ ) for 5 and $\mathbf{6}$.

* $2 \mid$ coefficient $\left.\right|^{2}>0.2$

The lowest energy transition in $\mathbf{3}$ is of the same character as the transitions in $\mathbf{1}$ and $\mathbf{2}$ and it occurs at $\lambda=538 \mathrm{~nm}(f=0.0006)$ (Table 2.11). The second set of absorption bands in the region 440-450 nm corresponds to transitions from HOMO, HOMO-1 to LUMO, LUMO+1 orbitals. The excited states 4,5 centered at $\lambda \sim 425 \mathrm{~nm}$, with low oscillator factors, mainly are $\mathrm{Rh}_{2}\left(\pi^{*}\right) \rightarrow \mathrm{Rh}_{2}\left(\sigma^{*}\right)$ transitions. The bands in the region 340380 nm are predicted to be strong and originate from HOMO, HOMO-1 to the low lying orbitals including LUMO+1 to LUMO+4 orbitals. Similarly to $\mathbf{5}$ and 6, the first two electronic transitions for 7 are mainly HOMO and HOMO-1 to LUMO occurring at $\lambda=$ 413 and $388 \mathrm{~nm}(f=0.0024$ and 0.0008 , respectively). These hypsochromic shifts, as compared to $\mathbf{3}$, are also due to the larger HOMO-LUMO energy gap. The excited states 3-5 arise from HOMO, HOMO-1 to LUMO+1 and LUMO+2 transitions in the region $340-360 \mathrm{~nm}$, and have similar characters and energies to those in $\mathbf{5}$ and $\mathbf{6}$.

In the orthometalated complex 4, the lowest energy transition at $442 \mathrm{~nm}(f=0.0223)$ corresponds to HOMO-4 and HOMO to LUMO transitions, rendering it $\mathrm{Rh}_{2}\left(\pi^{*}\right) \rightarrow \mathrm{Rh}_{2}\left(\sigma^{*}\right) \mathrm{MC}$ in character (Table 2.12). The absorption at $\sim 360 \mathrm{~nm}$ involves a series of transitions from orbitals including the HOMO-4 and HOMO $\rightarrow$ LUMO and thus they have dual LMCT and MC characters. The strong absorptions at $\sim 320 \mathrm{~nm}$ are mainly transitions from orbitals with both bridging ligand and metal contributions to the LUMO, thus also rendering them LMCT/MC in character but with much stronger oscillator factors as compared to the transitions at $\sim 360 \mathrm{~nm}$. Remarkably, in the methyl isocyanide analog 8, the lowest energy transition is expected at 376 nm with a very strong oscillator factor $f=0.2222$; this is mainly the $\mathrm{HOMO}_{\mathrm{Rh}_{2}}(\sigma) \rightarrow \mathrm{LUMO} \mathrm{Rh}_{2}\left(\sigma^{*}\right)$ transition and it
has a high molar absorptivity because it is allowed by the Laporte rules ( $\sigma_{\mathrm{g}} \rightarrow \sigma_{\mathrm{u}}$ orbital transition). The absorption shoulder at $\sim 310 \mathrm{~nm}$ arises from transitions from the HOMO to the vacant LUMO and LUMO+1 orbitals, whereas the absorption at $\sim 290 \mathrm{~nm}$ involves transitions from the HOMO to orbitals ranging from LUMO+2 to LUMO+4. Depopulation of the high energy $\mathrm{HOMO} \mathrm{Rh}_{2}(\sigma)$ orbital essentially induces cleavage of the $\mathrm{Rh}-\mathrm{Rh}$ bond, which explains the instability of compound $\mathbf{8}$ (vide supra).

## Infrared spectroscopy

A summary of the $v(\mathrm{NC})$ stretching frequencies for 5-8, and other reported $\mathrm{Rh}(\mathrm{II})$ and $\mathrm{Rh}(\mathrm{I})$ isocyanide compounds is provided in Table 2.13. As explained in the computational section (vide supra), the strength of the CN bond (and thus the stretching frequencies) in methyl isocyanide can be influenced by two interdependent factors: on the one hand, methyl isocyanide donates electron density to the $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbitals from its $\sigma^{*}(\mathrm{CN})$ orbital (HOMO), which is antibonding in character, ${ }^{138}$ this fact is expected to increase the $v(\mathrm{NC})$ stretching frequency as compared to free $\mathrm{CH}_{3} \mathrm{NC} .{ }^{139}$ Conversely, as a good $\pi$-acceptor, methyl isocyanide can accept electron density by backbonding from the Rh-Rh centers into the low lying $\pi^{*}$ molecular orbital, which results in elongation of the CN bond and a decrease in the $v(\mathrm{NC})$ stretching frequencies as compared to free $\mathrm{CH}_{3} \mathrm{NC}$ (similar to $\pi$-backbonding for $\mathrm{CO},{ }^{75,79-80}$ e.g., $v(\mathrm{CO})$ in $\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CC}_{3} \mathrm{H}_{7}\right)_{4}(\mathrm{CO})_{2}{ }^{79}$ and cis$\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{CO})\left(\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}\right)\right]$ is shifted to $2095 \mathrm{~cm}^{-1}$ and $2028 \mathrm{~cm}^{-1}$, respectively, as compared to $2143 \mathrm{~cm}^{-1}$ for free CO . In the case of compounds $\mathbf{5 - 8}$ (Table 2.13), the net result is a large shift for $v(\mathrm{NC})$ by $\sim 60-80 \mathrm{~cm}^{-1}$ to higher frequencies as compared to $\mathrm{CH}_{3} \mathrm{NC}$, ${ }^{139}$ which reflects the dominant effect of $\sigma$-donation from the methyl isocyanide groups to the $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbital in these complexes. ${ }^{80}$

[^1]In dirhodium complexes with ax isocyanide groups only, e.g., $\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4} \cdot 2 \mathrm{CNC}_{6} \mathrm{H}_{5}, \mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4} \cdot 2\left(\mathrm{NCBu}^{t}\right)$, there is a moderate shift of $v(\mathrm{NC})$ of $\sim 20 \mathrm{~cm}^{-1}$ to higher frequencies relative to the unperturbed isocyanide molecules ${ }^{84,140}$ (Table 2.13). In the case of the methyl isocyanide complexes 5-8, however, the effect is more pronounced due to the $\sigma$-donation of both axially and equatorially bound isocyanide groups. Analogous large shifts of $v(\mathrm{NC})$ by $\sim 80 \mathrm{~cm}^{-1}$ to higher frequencies have been reported for other dirhodium complexes with eq isocyanide groups, e.g., $\left[\mathrm{Rh}_{2}(\mathrm{pz})_{2}\left(\mathrm{CNBu}^{t}\right)_{4}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}$, $\left[\mathrm{Rh}_{2}\left(p-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{NC}\right)_{8} \mathrm{I}_{2}\right]\left[\mathrm{PF}_{6}\right]_{2}$, $\left[\mathrm{Rh}_{2}\left(\mathrm{CNC}_{6} \mathrm{H}_{11}\right)_{8} \mathrm{Cl}_{2}\right]\left[\mathrm{BF}_{4}\right]_{2}$ and others (Table 2.13). This $\sigma$-donation from the eq bonds has a substantial effect, as it is well established for compounds with $\mathrm{Rh}-\mathrm{Rh}$ bonds that the eq bonds to the Rh atoms are stronger than the ax interactions for the same ligand. Moreover, the strong $\sigma$-donation from the methyl isocyanide groups to the $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbital for $\mathrm{Rh}(\mathrm{II})$ complexes is also corroborated by the fact that the $\mathrm{v}(\mathrm{NC})$ is smaller in $\mathrm{Rh}(\mathrm{I})$ complexes, as in these cases, the $\pi$-backbonding, which results in a weakening of the CN bond, is more prominent, e.g., the last two $\mathrm{Rh}(\mathrm{I})$ isocyanide compounds listed in Table 2.13. ${ }^{92}$

For complexes 1-4, the stretching frequencies $v(\mathrm{CN})$ of $\mathrm{CH}_{3} \mathrm{CN}$ also shift to higher frequencies by $\sim 60-80 \mathrm{~cm}^{-1}$ (Table 2.14) as compared to free $\mathrm{CH}_{3} \mathrm{CN}\left(2253 \mathrm{~cm}^{-1}\right)$ which indicates a strengthening of the CN bond attributed to $\sigma$-donation from the nitrogen lone pair of the acetonitrile, which is antibonding in character, to the metal orbitals. ${ }^{141}$

## Electrochemistry

The electrochemical data for 1-8 are summarized in Table 2.15 and representative cyclic voltammograms are displayed in Figure 2.20 (for $\mathbf{2}$ and 6). The dirhodium compounds 13 and 5-7, supported by N-N type bridging ligands, exhibit two metal-centered oneelectron reductions and two one-electron oxidation processes (the first oxidation event is reversible). There is a second reduction at $\sim-1.20 \mathrm{~V}$ unlike the series of dirhodium substituted tetraformamidinate complexes reported by Ren et al., ${ }^{143}$ an indication of the better $\pi$-accepting ability of both $\mathrm{CH}_{3} \mathrm{NC}$ and $\mathrm{CH}_{3} \mathrm{CN}$ vs. the formamidinate groups. The second reductions for 5-7 are irreversible, however, an indication that the doubly reduced species for these electron-rich adducts are unstable. Furthermore, the oxidation processes of 1-3 and 5-7 shift to higher potentials as compared to $\mathrm{Rh}_{2}(\mathrm{DPhF})_{4}$, which further supports the effect of the $\pi$-accepting ability of the $\mathrm{CH}_{3} \mathrm{NC}$ and $\mathrm{CH}_{3} \mathrm{CN}$ ligands. In this respect, compounds 1-3 are easier to oxidize than the methyl isocyanide analogs 5-7, respectively, which attests to the improved $\pi$-accepting ability of $\mathrm{CH}_{3} \mathrm{NC}$ relative to

$\mathrm{CH}_{3} \mathrm{CN}$. Also, as expected, the methyl isocyanide analogs 5-7 are more difficult to reduce than the respective acetonitrile adducts $\mathbf{1 - 3}$ (the potentials for 5-7 shift to more negative values by $\sim 0.15 \mathrm{~V}$; Table 2.14 ) owing to the enhanced $\sigma$-donating ability of $\mathrm{CH}_{3} \mathrm{NC}$ as compared to $\mathrm{CH}_{3} \mathrm{CN}$, which renders the dirhodium core more electron-rich in the isocyanide series.

The axial isocyanide adduct $\mathrm{Rh}_{2}(\mathrm{DPhF})_{4}\left(\mathrm{CNC}_{6} \mathrm{H}_{5}\right)$ is not reduced within the negative potential limit of $\mathrm{CH}_{2} \mathrm{Cl}_{2}(-1.8 \mathrm{~V})$ in contrast to $\mathrm{Rh}_{2}(\mathrm{DPhF})_{4}$, which is reduced at -1.21 V under the same experimental conditions. ${ }^{82}$ Compounds $\mathbf{1}$ and $\mathbf{5}$ undergo more facile oxidations, as compared to $\mathbf{2}$ and 6, respectively, which is ascribed to the strong electron-withdrawing ability of the fluorine substituents on the formamidinate bridging ligands of the latter (based on the calculations, there is significant contribution to the HOMO from the bridging formamidinate ligands, Tables 2.5-2.7); similar trends were observed for the substituted $\mathrm{Rh}_{2}(\mathrm{R}-\mathrm{DPhF})_{4}$ series reported by Ren et al., ${ }^{143}$ but the differences in the reduction potentials between $\mathbf{1 , 2}$ and 5, $\mathbf{6}$ are much smaller, findings that are corroborated by the proximity between the LUMO orbitals of each set of complexes (Figure 2.19).

In the case of 4 , there is only one reversible oxidation at $\sim+1.54 \mathrm{~V}$, whereas this oxidation is shifted to $\sim+1.23 \mathrm{~V}$ for $\mathbf{8}$, indicating the destabilization of the HOMO. This oxidation is assigned to the $\mathrm{Rh}_{2}(\mathrm{II}, \mathrm{II}) / \mathrm{Rh}_{2}(\mathrm{II}, \mathrm{III})$ redox couple as in the case of cis$\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)_{2}\right]_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}$. No reduction was observed within the solvent limit for compound 4. A reduction for $\mathbf{8}$ occurs at $\sim-1.38 \mathrm{~V}$ but the irreversibility of the process indicates the instability upon reduction. The electrochemical behavior of $\mathbf{4}$ and $\mathbf{8}$, with
respect to reduction, is attributed to the strong $\sigma$-donating ability of the phosphine groups, ${ }^{81}$ which increases the electron density of the dirhodium core.

## Discussion

Two series of partial paddlewheel dirhodium compounds supported by $\sigma$-donating bridging $\mathrm{N}-\mathrm{N}$ or orthometalated phosphine ligands and either monodentate acetonitrile (1-4) or methyl isocyanide (5-8) groups in the unoccupied eq/ax positions were synthesized and investigated by X-ray crystallography, ${ }^{1} \mathrm{H},{ }^{31} \mathrm{P}$ NMR, electronic and infrared spectroscopies, cyclic voltammetry and theoretical calculations. In each series, the dirhodium core is supported by substituted formamidinates, triazenide or phosphine bridging groups. The substitution of the acetonitrile for methyl isocyanide ligands in 5-8 leaves the dirhodium core framework intact but results in substantial differences in the structural, spectrochemical and electrochemical behavior of the two classes of compounds. The findings from the X-ray crystallography, the electronic and infrared spectroscopies as well as the cyclic voltammetric and computational studies nicely converge and support the conclusions presented for the two series of complexes.

Compounds 5-8 are unprecedented partial paddlewheel $\mathrm{Rh}_{2}$ (II,II) compounds with a single metal-metal bond, with four eq and two ax positions occupied by methyl isocyanide ligands. The substitution of the $\mathrm{CH}_{3} \mathrm{CN}$ ligands with $\mathrm{CH}_{3} \mathrm{NC}$ results in marked differences in the corresponding distances between the two series 1-4/5-8 and allows for pertinent correlations that reflect the differences in the electronic structures of the monodentate ligands. The distances to the atoms engaged in short contacts with the $\mathrm{Rh}_{2}$ (II,II) units for $\mathbf{1 - 8}$ are summarized in Tables 2.16 and 2.17. It is important to note

that, in contrast to compounds 5-8, which are the first of their kind to be prepared by substitutions of the ax/eq monodentate ligands with methyl isocyanide, the few reported $\mathrm{Rh}_{2}$ (II,II) compounds with isocyanide groups occupying eq positions (Table 2.18) were synthesized by oxidative addition of halogens to $\mathrm{Rh}(\mathrm{I})$ isocyanide precursors ${ }^{93,94}$ or by the reaction of $\mathrm{Rh}(\mathrm{I})$ and $\mathrm{Rh}(\mathrm{III})$ mononuclear complexes. ${ }^{92}$ These compounds exhibit significantly different structural parameters than those found for 5-8 (Tables 2.16, 2.17). The dearth of the type of compounds of the type in this study is likely related to the fact that the stabilization of isocyanide metal-metal bonded compounds is non-trivial due to the non-innocent character of the isocyanide ligands, which leads to reduction of the metal centers and cleavage of the metal-metal bonds. ${ }^{84}$

Dirhodium coordination sphere, $\sigma$-bonding and $\pi$-backbonding in 1-8
It is notable that the Rh-Rh bond distances in 5-7 are elongated by up to $\sim 0.07 \AA$ relative to 1-3 (Table 2.16), respectively, and by $\sim 0.10 \AA$ in $\mathbf{8}$ as compared to 4 (Table 2.17), which indicates stronger interactions between the ax $\mathrm{CH}_{3} \mathrm{NC}$ ligands and the rhodium centers in the isocyanide series. This fact is also confirmed by the shorter Rh-C (ax $\mathrm{CH}_{3} \mathrm{NC}$ ) bond distances in 5-8 as compared to the Rh-N distances in 1-4 (Tables $2.16,2.17)$. The aforementioned findings are the result of two interdependent factors, which are reflected in the differences in the MOs of the two ligands. As noted earlier, the superior $\sigma$-donating ability of $\mathrm{CH}_{3} \mathrm{NC}$ relative to $\mathrm{CH}_{3} \mathrm{CN}$ is attributed to the fact that the HOMO of $\mathrm{CH}_{3} \mathrm{NC}$ is at higher energy than that of $\mathrm{CH}_{3} \mathrm{CN}$, whereas the enhanced $\pi$ accepting ability of $\mathrm{CH}_{3} \mathrm{NC}$ is due to the lower lying LUMO+1, LUMO+2 (Figure 2.10) orbitals. On the one hand, the strong $\sigma$-donation from the ax $\mathrm{CH}_{3} \mathrm{NC}$ groups to the $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbitals results in elongation of the Rh-Rh bond distances ${ }^{145}$ and shortening of the CN bond distances in $\mathrm{CH}_{3} \mathrm{NC}$ (the distances in the 5-8 are shorter than in the free ligand; Tables $2.16,2.17$ ) due to the $\pi^{*}$ antibonding character of the HOMO for $\mathrm{CH}_{3} \mathrm{NC}$. On the other hand, the donation of electron density from the $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ orbitals to the lowlying $\pi^{*}$ orbitals of the $\mathrm{CH}_{3} \mathrm{NC}$ ligands, due to the good $\pi$-accepting ability of $\mathrm{CH}_{3} \mathrm{NC}$, results in a reduction of the $\mathrm{Rh}-\mathrm{Rh}$ bond distances and elongation of the CN bonds. The net elongation of the $\mathrm{Rh}-\mathrm{Rh}$ bond distances in 5-8 and the shortening of the CN bonds by $\sim 0.02-0.04 \AA$ as compared to free $\mathrm{CH}_{3} \mathrm{NC}$ (Tables $2.16,2.17$ ) strongly suggest that the $\sigma$-donation of the ax $\mathrm{CH}_{3} \mathrm{NC}$ ligands is more dominant than the backbonding in 5-8. This
conclusion is also clearly corroborated by the $v(\mathrm{CN})$ frequencies of the methyl isocyanide groups in 5-8, which are higher by $V \sim 60-80 \mathrm{~cm}^{-1}$ as compared to free methyl isocyanide (Table 2.13); as explained earlier, this is due to donation of electron density from the $\sigma^{*} \mathrm{NC}$ antibonding HOMO orbital to the $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbitals of the complexes, thus rendering the NC bonds in the bound methyl isocyanide groups shorter than the free ligand (Tables 2.16, 2.17). A similar shortening of the CN bonds in $\mathrm{CH}_{3} \mathrm{CN}$ is also observed for the acetonitrile series 1-4 (Table 2.16). The strengthening of the CN bonds in 1-4 is also in agreement with the observed increase in the stretching frequencies $v(\mathrm{CN})$ by $\sim 60-80 \mathrm{~cm}^{-1}$ of the bound ligand as compared to free $\mathrm{CH}_{3} \mathrm{CN}$ (Table 2.14). ${ }^{141}$ The contraction of the CN bonds for the bound $\mathrm{CH}_{3} \mathrm{CN}$ groups in $\mathbf{1 - 4}$, however, is less than the corresponding one in $\mathbf{5 - 8}$, as compared to the free ligands in each case (Tables 2.16, 2.17), reflecting the better $\sigma$-donating ability of $\mathrm{CH}_{3} \mathrm{NC}$ as compared to $\mathrm{CH}_{3} \mathrm{CN}$.

Apart from the aforementioned $\mathrm{Rh}-\mathrm{Rh}$ and CN distances in 1-8, of pertinence to this discussion are the Rh-N and Rh-C distances in 1-4 and 5-8, respectively. Due to the smaller covalent radius of N vs. C , the $\mathrm{Rh}-\mathrm{N}\left(\mathrm{CH}_{3} \mathrm{CN}\right)$ distances in 1-4 would be expected to be shorter than the $\mathrm{Rh}-\mathrm{C}\left(\mathrm{CH}_{3} \mathrm{NC}\right)$ distances in 5-8, in the absence of $\pi$ backbonding. In our series, however, the bond distances Rh-C $\left(\mathrm{CH}_{3} \mathrm{NC}\right)$ in 5-8 are considerably shorter as compared to $\mathrm{Rh}-\mathrm{N}\left(\right.$ to $\left.\mathrm{CH}_{3} \mathrm{CN}\right)$ in 1-4 (Tables 2.16, 2.17), which strongly supports the presence of significant $\pi$-backbonding in the case of the methyl isocyanide series. An analogous shortening of the Rh-C bond distances has been observed for other reported dirhodium isocyanide complexes (Table 2.18) for which the Rh-C bond distances are typically in the range 1.98-2.1 $\AA$, i.e., shorter by $0.20-0.5 \AA$
than the Rh-C bond distances in dirhodium complexes with weak $\pi$-donor molecules such as (-)-trans-caryophyllene $(\sim 2.46,2.62 \AA),{ }^{146}$ other olefins, substituted alkynes, benzene and hexamethylbenzene, polycyclic aromatic hydrocarbons, and the geodesic polyarene corannulenes and hemibuckminsterfullerenes which exhibit considerably longer ax Rh-C bonds ( $\sim 2.5-2.7 \AA$ ). In agreement with the presence of considerable $\pi$ backbonding from $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ to $\pi^{*}\left(\mathrm{CH}_{3} \mathrm{NC}\right)$ and shorter $\mathrm{Rh}-\mathrm{C}$ bond distances in 5-8, the $\mathrm{Rh}-\mathrm{Rh}$ bond distances are also longer in the latter series as compared to 1-4 (Tables 2.16, 2.17). ${ }^{141}$ The presence of significant $\pi$-backbonding from the dirhodium core to the methyl isocyanide groups in 5-8 accounts for the more positive oxidation potentials of 5$\mathbf{8}$ with respect to 1-4 (Table 2.15), as there is reduced electron density on the dirhodium core in 5-8, thus rendering it more difficult to oxidize the isocyanide series. On the other hand, the more negative reduction potentials for 5-8 are in accord with the enhanced $\sigma$ donation of $\mathrm{CH}_{3} \mathrm{NC}$.

As reported by Christoph et al. and Eagle et al., both the $\sigma$-donor and $\pi$-acceptor abilities of the ligands have an impact on the Rh-Rh and Rh-L (ax) structural parameters, ${ }^{22,133}$ which is clearly demonstrated by comparing $1-4$ with 5-8. The strong trans influence that gives rise to the inverse relationship of the $\mathrm{Rh}-\mathrm{Rh}$ and $\mathrm{Rh}-\mathrm{N} / \mathrm{Rh}-\mathrm{C}$ (ax) distances, ${ }^{22,147}$ namely isocyanide adducts with the shorter Rh-C ax bonds exhibit longer $\mathrm{Rh}-\mathrm{Rh}$ distances as compared to the acetonitrile series with shorter $\mathrm{Rh}-\mathrm{Rh}$ and longer ax Rh-N distances (Tables 2.16, 2.17). Furthermore, the trans influence is also obvious when comparing the $\mathrm{Rh}-\mathrm{L}$ (eq) monodentate ligand and the $\mathrm{Rh}-\mathrm{N}$ (bridge) distances between the two series. The shorter bond distances Rh-C (eq $\mathrm{CH}_{3} \mathrm{NC}$ ) in 5-7,
indicating the stronger interactions between the Rh centers and the eq $\mathrm{CH}_{3} \mathrm{NC}$ ligands due to $\pi$-backbonding, result in the elongation of the trans $\mathrm{Rh}-\mathrm{N}$ (bridging group) distances by $\sim 0.05 \AA$ as compared to their $\mathrm{CH}_{3} \mathrm{CN}$ analogs $\mathbf{1 - 3}$ with weaker $\mathrm{Rh}-\mathrm{N}$ eq bonds to the acetonitrile ligands. The short bond distances $\mathrm{Rh}-\mathrm{C}(\mathrm{eq} \mathrm{CH} 3 \mathrm{NC})$ in 5-7 (and thus stronger bonds) are also supported by the absence of $\mathrm{CH}_{3} \mathrm{NC}$ ligand exchange with the solvent in the ${ }^{1} \mathrm{H}$ NMR spectra of the isocyanide complexes even after 1 week (e.g., Figure 2.7). Short Rh-C $\left(\mathrm{CH}_{3} \mathrm{NC}\right)$ contacts are also encountered in both isomers of $\mathbf{8}$ with remarkably short Rh-C (ax $\mathrm{CNCH}_{3}$ ) bond distances that are only $\sim 0.02 \AA$ longer than the $\mathrm{Rh}-\mathrm{C}\left(\mathrm{eq} \mathrm{CNCH}_{3}\right.$ ) distances (Table 2.17). To the best of our knowledge, the latter finding is unprecedented for $\mathrm{Rh}_{2}(\mathrm{II}, \mathrm{II})$ compounds, as it is well-known that the ax ligands typically establish weaker contacts with the dirhodium core as compared to the same identity eq ligands, e.g., in the case of $\mathbf{1 - 3}$ the contacts to the eq $\mathrm{CH}_{3} \mathrm{CN}$ groups are up to $0.2 \AA$ shorter than the ax distances, and in the cases of $4-7$, the eq contacts are shorter by $\sim 0.10 \AA$. In particular, the Rh-N (ax $\mathrm{CH}_{3} \mathrm{CN}$ ) bond distances (2.202(6) and $2.196(6) \AA$ ) for compound 4 are much longer than $\mathrm{Rh}-\mathrm{N}\left(\right.$ eq $\left.\mathrm{CH}_{3} \mathrm{CN}\right)$ (in the range 2.104(6)-2.142(6) $\AA)$. The extremely short Rh-C ( $\mathrm{ax} \mathrm{CH}_{3} \mathrm{NC}$ ) bonds in $\mathbf{8}$ as well as the considerably shorter Rh-C (ax $\mathrm{CH}_{3} \mathrm{NC}$ ) in 5-7, as compared to other dirhodium compounds with ax C atom donors, ${ }^{146146}$ are correlated to the increased electron density on the dirhodium core (arising from the strong $\sigma$-donation of the orthometalated phosphine bridging groups, which increases the degree of $\pi$-backbonding to the $\pi$ acceptor isocyanide ligands and thus strengthens the $\mathrm{Rh}-\mathrm{C}$ bonds). In this respect, for example, the Rh-C ( $\mathrm{ax} \mathrm{CH}_{3} \mathrm{NC}$ ) bond distances in 5-7 are shorter than the distances in
the tetra-acetate adducts with isocyanide $\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4} \cdot 2 \mathrm{~L}\left(\mathrm{~L}=2 \mathrm{CNC}_{6} \mathrm{H}_{4} \mathrm{~N}\left(\mathrm{CH}_{3}\right)_{2}\right.$, $\mathrm{CNC}_{6} \mathrm{H}_{5}, \mathrm{CNC}_{6} \mathrm{H}_{5} \mathrm{CF}_{3} ; \sim 2.14 \AA$ ) but longer than the corresponding ax distances in $\mathrm{Rh}_{2}(\mathrm{DPhF})_{4}\left(\mathrm{CNC}_{6} \mathrm{H}_{5}\right)$ and $\mathrm{Rh}_{2}(\mathrm{DPhF})_{4}\left(\mathrm{CNC}_{6} \mathrm{H}_{4} \mathrm{NC}\right) \mathrm{Rh}_{2}(\mathrm{DPhF})_{4}(\sim 1.99 \AA \text {; Table 10) })^{82}$ as well as in $\mathbf{8}\left(\sim 2.03 \AA\right.$; Table 2.17). The previous Rh-C $\left(a x \mathrm{CH}_{3} \mathrm{NC}\right)$ bond distances decrease in the order of increasing number of strong $\sigma$-donor formamidinate or phosphine bridging ligands bound to the dirhodium core, rendering it progressively more electron-rich and thus a better candidate for $\pi$-backbonding and shorter Rh-C (ax $\left.\mathrm{CH}_{3} \mathrm{NC}\right)$ distances. The higher degree of $\pi$-backbonding in the case of $\mathbf{8}$ as compared to 5-7 is also reflected by the lower $v(\mathrm{NC})$ frequency of the $\mathrm{CH}_{3} \mathrm{NC}$ groups in $\mathbf{8}$ (by $\sim 20-30$ $\mathrm{cm}^{-1}$; Table 2.13) vs. 5-7.

As previously detailed, the short $\mathrm{Rh}-\mathrm{C}\left(\mathrm{eq} \mathrm{CNCH}_{3}\right)$ contacts and the concomitant significant $\pi$-backbonding from the dirhodium unit to the $\mathrm{CH}_{3} \mathrm{NC}$ ligands in 5-7 relative to 1-3 lead to the stabilization of the $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ orbitals (due to the higher contribution from the low-lying $\pi^{*}$ orbitals of $\mathrm{CH}_{3} \mathrm{NC}$ in 5-7; Tables 2.4-2.7), which result in the $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ being of lower energy than that of the $\mathrm{Rh}_{2}(\sigma)$ level (Figures 2.11, 2.12). In the case of $\mathbf{8}$, however, apart from the strong eq $\mathrm{CH}_{3} \mathrm{NC}$ contacts, the strong Rh-C bonds with the ax $\mathrm{CH}_{3} \mathrm{NC}$ ligands, which are shorter by $0.05 \AA$ as compared to 5-7, greatly destabilize the $\mathrm{Rh}_{2}(\sigma)$ bond (Figure 2.14), which complies with the considerably longer Rh-Rh distances in 8 ( $\sim 2.76 \AA$; Table 9) as compared to 4, as well as with the observed relative instability of $\mathbf{8}$ in solution, as evidenced by the ${ }^{1} \mathrm{H},{ }^{31} \mathrm{P}$ NMR data (Figure 2.8) and the ESI-MS fragmentation pattern. The previous findings are in accord with the strong trans influence of the ax $\mathrm{Rh}-\mathrm{C}$ bonds on the $\mathrm{Rh}-\mathrm{Rh}$ bond in 8 . Similarly, the
shorter Rh-C (eq $\mathrm{CNCH}_{3}$ ) contacts in $\mathbf{8}$ exert a strong trans influence on the bridging orthometalated ligands, thus resulting in elongation of the Rh-C (bridge) and Rh-P bonds by $\sim 0.1$ and $0.08 \AA$, respectively (Table 9), as compared to the orthometalated adducts cis- $\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\right] \cdot 2 \mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}$ and cis$\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\right] \cdot 2 \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$ with bridging carboxylate groups. ${ }^{134}$ Molecular orbital energy levels, spectroscopic and electrochemical studies for 1-8 The stronger $\sigma$-donating ability of the ax isocyanide groups in 5-8 leads to the destabilization of the $\operatorname{LUMO~}_{2} \mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbitals (Figures 2.11, 2.12 and 2.14) in 5-8 vs. 1-4. Furthermore, the non-bonding HOMOs of 5-7 are stabilized as compared to the antibonding HOMOs of their $\mathrm{CH}_{3} \mathrm{CN}$ analogs $\mathbf{1 - 3}$ (Figures 2.11, 2.12). The aforementioned shifts in the HOMO/LUMO relative energy levels, resulting in larger HOMO-LUMO energy gaps in 5-8 vs. 1-4 (Figures 2.11, 2.12), clearly account for the experimentally observed hypsochromic shifts of the lowest energy transitions in the visible spectra ( $\sim 360-450 \mathrm{~nm}$ ) of the isocyanide series 5-8, by $\sim 80-100 \mathrm{~nm}$, relative to the corresponding acetonitrile analogs 1-4 (comparisons between $\mathbf{1}$ and 5, 2 and 6, 3 and 7, 4 and 8; Table 2.3); an increase in the lowest energy bands of the dirhodium core with increasing donor strength of the ax ligands was previously recorded. ${ }^{148}$ Importantly, the results from the TD-DFT calculations (Tables 2.9 - 2.12 and Figures 2.15, 2.16) provide strong support for the previous hypsochromic shifts of the low energy bands in the electronic spectra of 5-8 as compared to 1-4. In particular, in the case of 8, the TD-DFT calculations are not only in agreement with the experimentally observed hypsochromic shift of the low-energy MC band to 362 nm (from $\sim 478 \mathrm{~nm}$ in 4 ), but they also support the
nearly 20-fold increase of the band intensity in $\mathbf{8}\left(\varepsilon \sim 10^{4} \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ with respect to $\mathbf{4}(\varepsilon \sim 6$ x $10^{2} \mathrm{M}^{-1} \mathrm{~cm}^{-1}$; Table 2.3, Figure 2.9d) based on the calculated strong oscillator factor for 8 (Table 2.12). The MC band at 362 nm , which is assigned to the $\mathrm{HOMO}_{\mathrm{Rh}}^{2}(\sigma) \rightarrow$ LUMO $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ transition in 8, exhibits a high molar absorptivity, as compared to a typical d-d electronic transition because it is allowed by the Laporte rules ( $\sigma_{\mathrm{g}} \rightarrow \sigma_{\mathrm{u}}$ transition). The stronger interactions of the dirhodium core with the ax $\mathrm{CH}_{3} \mathrm{NC}$ ligands increase the energy of the $\mathrm{Rh}_{2}(\sigma)$ orbital considerably, rendering it the HOMO in $\mathbf{8}$ (Figure 2.14) as opposed to 4 where the lowest energy transition is the $\mathrm{HOMO}_{\mathrm{Rh}}^{2}\left(\pi^{*}\right) \rightarrow \mathrm{LUMO}_{\mathrm{Rh}}^{2}\left(\sigma^{*}\right)$ and thus of considerably lower intensity (Figure 2.9d, Table 2.3). ${\mathrm{The} \mathrm{Rh}_{2}(\sigma) \text { orbital has been reported }}_{\text {a }}$ to become the HOMO for dirhodium tetracarboxylate complexes with strong ax ligands, e.g., phosphines. ${ }^{79,149-151}$ Larger energy gaps for the $\operatorname{MC~} \mathrm{Rh}_{2}\left(\pi^{*}\right) \rightarrow \mathrm{Rh}_{2}\left(\sigma^{*}\right)$ transitions were also rightfully anticipated by the TD-DFT calculations, which corroborate the hypsochromic shifts of the electronic transitions in 5-7 as compared to $\mathbf{1 - 3}$, respectively (in the range $425-440 \mathrm{~nm}$ for $\mathbf{1 - 3} \mathrm{vs} .295-300 \mathrm{~nm}$ for 5-7; Tables 2.9-2.12). Accordingly, the slight hypsochromic shift of the lowest energy HOMO-LUMO transition in $\mathbf{2}$ as compared to $\mathbf{1}$ (Table 2.3, Figure 2.9a) is in agreement with the TD-DFT calculations (Table 2.9) and is attributed to the greater stabilization of the HOMO (primarily of bridging formamidinate ligand character) in $\mathbf{2}$ (Figure 2.19) due to the electron-withdrawing F substituents on the formamidinate bridging ligands.

It is notable that the DFT calculations are also in excellent agreement with the findings from the electrochemical studies. In particular, the stabilization of the HOMO orbitals in compounds 5-7, as compared to $\mathbf{1 - 3}$ (Figure 2.19) is corroborated by the
higher oxidation potentials of the isocyanide series 5-7 vs. the acetonitrile analogs 1-3, respectively (Table 2.15); this is ascribed to the $\pi$-backbonding from the dirhodium core to the $\mathrm{CH}_{3} \mathrm{NC}$ groups. Correspondingly, the higher energy of the LUMO orbitals for compounds 5-7 (Figure 2.19) is in agreement with the isocyanide analogs 5-7 being more difficult than 1-3 to reduce as a result of the more electron-rich dirhodium cores in 5-7, arising from the superior $\sigma$-donating ability of $\mathrm{CH}_{3} \mathrm{NC}$ as compared to $\mathrm{CH}_{3} \mathrm{CN}$. Furthermore, the expected correlations are found by comparing the electrochemical behavior of $\mathbf{1}$ with $\mathbf{2}$ and $\mathbf{5}$ with $\mathbf{6}$, i.e., $\mathbf{1}$ and $\mathbf{5}$ more easily oxidized and less easily reduced than 2 and 6, respectively, which is reflected by the lower-lying LUMO and HOMO orbitals for $\mathbf{2}$ and $\mathbf{6}$ with respect to $\mathbf{1}$ and $\mathbf{5}$ (Tables 2.4 and 2.5, Figure 2.19) due to the strong electron withdrawing ability of the fluorine groups on the formamidinate bridging ligands.

## Concluding remarks

In this comprehensive investigation, two analogous classes of dirhodium compounds with two strong $\sigma$-donating bridging groups and eq/ax monodentate acetonitrile (1-4) or isocyanide (5-8) ligands were synthesized and characterized by X-ray crystallography, ${ }^{1} \mathrm{H},{ }^{31} \mathrm{P}$ NMR, electronic and infrared spectroscopies as well as electrochemical studies, the collective results of which are in agreement with the theoretical studies. The isocyanide analogs 5-8 are unprecedented with respect to their geometrical features and are a rarity in the metal-metal bond literature with isocyanide ligands given the synthetic challenges of isolating products that have not undergone reduction. The substitution of acetonitrile for isocyanide in the eq/ax positions leads to notable changes in the
isocyanide series 5-8 as compared to 1-4 and allows for intriguing correlations between the two classes of dirhodium compounds to be made. The combined experimental data gleaned from the crystallographic, spectroscopic and theoretical studies all converge to the conclusion that the improved $\sigma$-donating and $\pi$-accepting abilities of isocyanide $v s$. acetonitrile have a profound effect on the structural and spectroscopic features of 5-8. In particular, the longer Rh-Rh bonds (by up to $\sim 0.07 \AA$ ) in 5-8 vs. 1-4 are in agreement with the better $\sigma$-donation of the ax $\mathrm{CH}_{3} \mathrm{NC}$ as compared to $\mathrm{CH}_{3} \mathrm{CN}$; the latter conclusion is also supported by the short CN distances in $\mathrm{CH}_{3} \mathrm{NC}$ and the increase in the stretching frequencies $v(\mathrm{CN})$ by $\sim 60-80 \mathrm{~cm}^{-1}$ for the bound ligands in $\mathbf{5 - 8}$ vs. free $\mathrm{CH}_{3} \mathrm{NC}$. Furthermore, the short Rh-C (ax $\left.\mathrm{CH}_{3} \mathrm{NC}\right)$ distances in 5-8, which exert a strong trans influence on the Rh-Rh bonds, attest to the enhanced $\pi$-accepting ability of $\mathrm{CH}_{3} \mathrm{NC}$ as compared to $\mathrm{CH}_{3} \mathrm{CN}$. The significant $\pi$-backbonding from the dirhodium core to the isocyanide groups in $\mathbf{5 - 8}$ is also evidenced by the shorter bond distances Rh-C (eq $\mathrm{CH}_{3} \mathrm{NC}$ ), which result in elongation of the Rh -bridging group distances trans to the eq isocyanide groups, as compared to their $\mathrm{CH}_{3} \mathrm{CN}$ analogs $\mathbf{1 - 4}$ with longer $\mathrm{Rh}-\mathrm{N}$ (eq $\mathrm{CH}_{3} \mathrm{CN}$ ) bonds. In accord with the $\pi$-backbonding to the isocyanide groups for 5-8, are their more positive oxidation potentials and the lower energy levels of the HOMO orbitals as compared to $\mathbf{1 - 4}$. The more negative reduction potentials and the destabilization of the LUMO orbitals for 5-8 vs. 1-4 are consistent with the enhanced $\sigma$ donation of $\mathrm{CH}_{3} \mathrm{NC}$. Accordingly, the TD-DFT calculations are in excellent agreement with the larger HOMO-LUMO energy gaps in 5-7 vs. 1-3 as well as with the experimentally observed hypsochromic shifts of the lowest-energy transitions in the
isocyanide series 5-7 with respect to the corresponding acetonitrile analogs 1-3. Interestingly, for 8, the TD-DFT calculations corroborate the experimentally observed hypsochromic shift of the low energy MC band and the $\sim 20$-fold increase of the band intensity in $\mathbf{8}\left(\varepsilon \sim 10^{4} \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ with respect to 4. The latter increase originates from a Laporte allowed HOMO $\mathrm{Rh}_{2}(\sigma) \rightarrow$ LUMO $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ transition due to the increase in the energy of the $\mathrm{Rh}_{2}(\sigma)$ orbital with respect to $\mathbf{4}$, which renders it the HOMO in $\mathbf{8}$. This considerable destabilization of the $\mathrm{Rh}_{2}(\sigma)$ in $\mathbf{8}$ is attributed to the stronger interactions of the dirhodium core with the ax $\mathrm{CH}_{3} \mathrm{NC}$ ligands. These interactions account for the weaker Rh-Rh bond (by $\sim 0.1 \AA$ relative to the acetonitrile analog 4) and the remarkably short ax Rh-C $\left(\mathrm{CH}_{3} \mathrm{NC}\right)$ distances $(2.01-2.04 \AA)$ in $\mathbf{8}$, and, in fact the latter become comparable in length to the eq $\mathrm{Rh}-\mathrm{C}\left(\mathrm{CH}_{3} \mathrm{NC}\right)$ contacts which is an unprecedented structural feature among all reported dirhodium(II,II) compounds.

To this stage, two series of partial paddlewheel dirhodium complexes featuring two electron-rich bridging ligands with the cis configuration have been developed, namely the acetonitrile complexes 1-4 and their corresponding methyl isocyanide anologs 5-8. The strong electron donating ability of the bridging ligands renders the $\mathrm{CH}_{3} \mathrm{CN}$ ligands trans to them labile, and conversely, due to $\pi$-backbonding, leads to substitutional inertness for $\mathrm{CH}_{3} \mathrm{NC}$ ligands. To achieve the dark stability and photolability of the eq monodentate ligands for this type of dirhodium complexes, further tuning of the ligand field around the dimetal center is required. The use of less electron accepting ligands, e.g. $\mathrm{CF}_{3} \mathrm{NC}$ and $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NC}$ are promising for this purpose and these studies are currently in progress.

## CHAPTER III

## INVESTIGATION OF PARTIAL PADDLEWHEEL DIRHODIUM COMPLEXES WITH ELECTRON ACCEPTOR LIGANDS*

## Introduction

Photocatalytic reduction of $\mathrm{H}_{2} \mathrm{O}$ to generate $\mathrm{H}_{2}$ is one of the most promising and effective methods for meeting the demand for increasing global fuel consumption. Transition metal complexes hold great potential as molecular water reduction photocatalysts as exemplified by the extensive studies of $\mathrm{Ni}(\mathrm{II})^{64}, \mathrm{Co}(\mathrm{II}){ }^{152}, \operatorname{Pt}(\mathrm{II}){ }^{153}$, $\operatorname{Pd}(\mathrm{II}){ }^{154}, \operatorname{Rh}(\mathrm{III}){ }^{155}$ and $\mathrm{Mo}(\mathrm{III}){ }^{65}$ complexes. Among the aforementioned catalysts, mononuclear $\mathrm{Rh}($ III ) complexes represent one of the earliest examples in this category. ${ }^{156}$ A few years ago Bernhard and co-workers reported a multicomponent $\mathrm{H}_{2} \mathrm{O}$ reduction system, $\left[\operatorname{Rh}(\text { dtbbpy })_{3}\right]^{3+}$ (dtbbpy $=4,4$ '-di-tert-butyl-2,2'-bipyridine) as the catalyst and $\left[\operatorname{Ir}(\mathrm{f}-\mathrm{mppy})_{2}(\mathrm{dtbbpy})\right]^{+}(\mathrm{f}-\mathrm{mppy}=5-$ methyl-2-(4-fluorophenyl)pyridine) as the photosensitizer that achieves a turnover number (TON) of $>5000$ upon 22 h irradiation under optimal conditions. ${ }^{157}$ Another example relevant to the current study involves the series of dirhodium(II,II) complexes, cis-[ $\left.\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{~L})_{2}\right]\left[\mathrm{O}_{2} \mathrm{CCH}_{3}\right]_{2}$ $\left(\mathrm{L}=\mathrm{bpy}\right.$, phen; $\mathrm{bpy}=2,2^{\prime}$-bipyridine, phen $=1,10$-phenanthroline $)$ which were recently shown to act as catalysts for $\mathrm{H}_{2}$ evolution from $\mathrm{H}^{+}$in the presence of external photosensitizer, $\left[\operatorname{Ir}(\mathrm{ppy})_{2}(\mathrm{dtbbpy})\right]^{+}(\mathrm{ppy}=2$-phenylpyridine $)$ and the sacrificial electron donor triethylamine (TEA). ${ }^{14}$ It was proposed by the researchers that the reduced

[^2]photosensitizer (this reduction is achieved by TEA) undergoes electron transfer process to the $\mathrm{Rh}_{2}(\mathrm{II}, \mathrm{II})$ catalysts to generate the active catalysts upon light irradiation; the identities of the active catalysts, however, remain unknown. Interestingly, the performance of this multicomponent system depends on the concentration of the catalysts. For example, at the concentration of $16.7 \mu \mathrm{M}\left(\right.$ cis- $\left.\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\text { phen })_{2}\right]^{2+}\right)$, the TON for $\mathrm{H}_{2}$ production reached 2622 after 50 h of irradiation, which is the maximum efficiency for the system. Another series of excellent complexes in this vein are developed by Nocera and coworkers as shown earlier in chapter I. They were able to eliminate electron transfer steps between the sensitizer and the catalyst in the excited state because both the light absorber and the catalytic unit are in one molecule. ${ }^{15-17}$

The present work in this chapter focuses on the synthesis and characterization of series of $\quad c i s-\left[\mathrm{Rh}_{2}(\mu \text {-DTolF })_{2}(\mathrm{~L})_{2}\right]\left[\mathrm{BF}_{4}\right]_{2} \quad$ and $\quad c i s-\left[\mathrm{Rh}_{2}(\mu \text {-F-form })_{2}(\mathrm{~N}-\mathrm{N})_{2}\right]\left[\mathrm{BF}_{4}\right]_{2}$ complexes $(\mathrm{DTolF}=$ p-ditolylformamidinate, F -Form $=$ di-pfluorobenzylformamidinate; $\mathrm{N}-\mathrm{N}=$ chelating diimine ligands, dpq dipyrido[3,2-f:2',3'-h]-quinoxaline), dppz (dipyrido[3,2-a:2', $3^{\prime}$-c]phenazine) and dppn (benzo[i]dipyrido[3,2-a:2', 3'h]quinoxaline)). In addition, the computational modeling studies are also conducted for the better understanding of their photophysical properties. These complexes, the structural representation of which are depicted in Figure 3.1, were chosen based on our prior finding that $\mathrm{Rh}_{2}$ (form) $)_{4}$ (form $=$ formamidinate ligands with various substituents) exhibit highly reducing excited states capable of transferring electrons to alkyl halides via outer-sphere mechanism. The photophysical and redox properties of the new
complexes were also investigated, and the data reveal highly reducing and oxidizing ligand-to-ligand charge-transfer (LLCT) excited states.

Figure 3.1 Schematic representations of the molecular structures of selected complexes.

## Experimental section

## Starting materials

The precursor (RhClCOD) $)_{2}$ was purchased from Pressure Chemicals and used without further purification. The compounds $[\mathrm{Rh}(\mathrm{F}-\text { form })(\mathrm{COD})]_{2},[\mathrm{Rh}(\mathrm{DTolF})(\mathrm{COD})]_{2},{ }^{102} \mathrm{dpq}$ (dipyrido[3,2-f: $\left.2^{\prime}, 3^{\prime}-\mathrm{h}\right]-$ quinoxaline), dppz (dipyrido[3,2-a:2', $\left.3^{\prime}-\mathrm{c}\right]$ phenazine) and dppn (benzo[i]dipyrido[3,2-a:2', $3^{\prime}$ 'h]quinoxaline) ${ }^{158}$ were synthesized by published procedures. The synthesis of cis- $\left[\mathrm{Rh}_{2}(\mathrm{~F} \text {-form })_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ was achieved by adapting the published procedure for $c i s-\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} .{ }^{104}$ Acetonitrile was pre-dried over $3 \AA$ molecular sieves and distilled under a nitrogen atmosphere. All reactions were conducted using standard Schlenk-line techniques unless otherwise stated. Filtration and further manipulation of the products were conducted in air. cis $-\left[\mathbf{R h}_{2}(\mathbf{D T o l F})_{2}(\mathbf{d p q})_{2}\left(\mathbf{C H}_{3} \mathbf{C N}\right)\right]\left[\mathrm{BF}_{4}\right]_{2} \quad$ (9). A sample of cis$\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}(68 \mathrm{mg}, 0.063 \mathrm{mmol})$ was dissolved in 10 mL of $\mathrm{CH}_{3} \mathrm{CN}$ and combined with 20 mL of $\mathrm{CH}_{3} \mathrm{CN}$ suspended with $37 \mathrm{mg}(0.16 \mathrm{mmol})$ of the dpq ligand. The color of the solution changed gradually from red to dark brown and was refluxed under $\mathrm{N}_{2}$ for 48 h after which time it was concentrated to 5 mL and filtered through a medium frit to remove any insoluble materials. Addition of 20 mL of diethyl ether induced the precipitation of 68 mg of green product which was washed three times with 10 mL of diethyl ether and collected by filtration. It was dried under vacuum for 24 h (yield: $79 \%$ based on rhodium). ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}-d_{3}\right) \delta$ ppm: $9.02(\mathrm{~s}, \mathrm{dpq}), 8.88$ (dd, dpq), 8.79 (d, dpq), 8.29 (t, NCHN), 7.76 (dd, dpq), 7.10 (dd, phenyl H of DTolF), 2.28 (s, $-\mathrm{CH}_{3}$ of DTolF), $1.96\left(\mathrm{~s}, \mathrm{CH}_{3} \mathrm{CN}\right)$. ESI-MS: $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{dpq})_{2}\right]^{2+}$, 558.08. Anal.

## Instrumentation and methods

X-ray data sets for 10, and 12-14 were collected on a Bruker CCD APEX diffractometer with graphite monochromated $\mathrm{Mo} \mathrm{K} \alpha$ radiation $(\lambda=0.71073 \AA)$. X-ray data for $\mathbf{9}$ and $\mathbf{1 1}$ were collected at beamline 15-ID-B at the Advanced Photon Source at Argonne National Laboratory using synchrotron radiation $(\lambda=0.41328 \AA$ ). A hemisphere of data for $\mathbf{1 0}$, 12-14 were collected by a combination of four sets of X-ray exposures. Each set used a different $\phi$ angle for the crystals and covered $0.5^{\circ}$ in $\omega$ for $\mathbf{1 0}$ and $\mathbf{1 4}, 0.3^{\circ}$ for $\mathbf{1 2}$ and $\mathbf{1 3}$. The exposure times were 20 s for $\mathbf{1 0}, \mathbf{1 2}$ and $\mathbf{1 4}$ and 30 s for $\mathbf{1 3}$. Crystal data for $\mathbf{9}$ and $\mathbf{1 1}$ were collected by a combination of two sets of X-ray exposures. The first set of data covers the whole sphere of the crystal whereas the second set of data covers the half sphere with an exposure time of 0.3 s . Crystal decay was monitored by analyzing duplicate reflections and was found to be less that $1 \%$, therefore no decay corrections were applied.

Cyclic voltammetry and Uv-vis spectroscopic measurements were done in the similar fashion to the ones in the previous chapter II. The methods for the computational studies are also detailed in the same chapter.

## Results and discussion

## Synthesis and solution characterization

The complex cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]^{2+}$ reacts with the diimine ligands dpq, dppz, and dppn to produce cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{dpq})_{2}\right]^{2+}(\mathbf{9})$, cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{dppz})_{2}\right]^{2+}(\mathbf{1 0})$, and $c i s-\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{dppn})_{2}\right]^{2+}(\mathbf{1 1})$, respectively. Similarly, cis- $\left[\mathrm{Rh}_{2}(\text { F-form })_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]^{2+}$ was used to produce $c i s-\left[\mathrm{Rh}_{2}(\mathrm{~F}-\text { form })_{2}(\mathrm{dpq})_{2}\right]^{2+}(\mathbf{1 2})$, cis- $\left[\mathrm{Rh}_{2}(\mathrm{~F}-\text { form })_{2}(\mathrm{dppz})_{2}\right]^{2+}(\mathbf{1 3})$,
and cis- $\left[\mathrm{Rh}_{2}(\mathrm{~F} \text {-form })_{2}(\mathrm{dppn})_{2}\right]^{2+}(\mathbf{1 4})$. The schematic representations of the structures of 9-11 and 12-14 are shown in Figure 3.1.

The reaction of cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ with 2.2 equivalents of dppz was monitored by ${ }^{1} \mathrm{H}$ NMR spectroscopy as a function of reaction time; the aromatic regions of the spectra collected after 7 and 35 hours are shown in Figure 3.2. After refluxing for 7 hours, the ${ }^{1} \mathrm{H}$ NMR spectrum is consistent with a mixture of the starting material cis$\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ and a new product (labeled as * and $\dagger$, respectively, in Figure 3.2a). The new product, labeled $\dagger$, exhibits resonances from bound dppz ligand at $\delta=9.84,9.43,8.51,8.25,8.17 \mathrm{ppm}$, together with a new triplet at $\delta=7.92 \mathrm{ppm}$ arising from the NCHN on the $[\mathrm{DTolF}]^{-}$ligand. The ratio between the integrations of the resonances at 9.84 and 7.92 ppm is approximately $1: 1$, consistent with the formation of the mono-dppz intermediate product cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3,4}(\mathrm{dppz})\right]\left[\mathrm{BF}_{4}\right]_{2}(\dagger)$. This species with the dppz ligand bound in an eq-eq fashion is similar to those reported for the related complexes cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3,4}(\mathrm{bpy})\right]\left[\mathrm{BF}_{4}\right]_{2}$ and cis$\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3,4}(\right.$ phen $\left.)\right]\left[\mathrm{BF}_{4}\right]_{2},{ }^{129}$ but no eq $\mathrm{CH}_{3} \mathrm{CN}$ resonances were observed in this case, presumably due to their fast exchange with the $\mathrm{CD}_{3} \mathrm{CN}$ molecules.

Figure 3.2 Aromatic region of the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra of the products of the reaction between cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left(\mathrm{BF}_{4}\right)_{2}$ and 2.2 equiv of dppz in $\mathrm{CD}_{3} \mathrm{CN}$ after refluxing in $\mathrm{CH}_{3} \mathrm{CN}$ for (a) 7 hours and (b) 35 hours, where $*=$ cis$\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left(\mathrm{BF}_{4}\right)_{2}, \dagger=$ cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3-4}\left(\mathrm{dppz}^{2}\right)\right]\left(\mathrm{BF}_{4}\right)_{2}$, and $\ddagger=$ 10.

After 35 hours the resonance at 7.52 ppm (labeled *) disappeared, indicating total consumption of the cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ starting material. Moreover, the intensities of the resonances for the mono-dppz cis$\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3,4}(\mathrm{dppz})\right]\left[\mathrm{BF}_{4}\right]_{2}$ intermediate decreased ( $\dagger$ ), with concomitant appearance of a new set of dppz resonances at $8.97,8.81,8.05,7.84,7.80 \mathrm{ppm}$ and bridgehead protons (NCHN) of [DTolF] at 8.31 ppm , corresponding to the final product (labeled $\ddagger$ in Figure 3.2b). The integration ratio between the resonances at 8.97 and at 8.31 ppm is $\sim 2: 1$, consistent with the formation of final product $\mathbf{1 0}$. Three days of refluxing followed by purification led to the generation of a single final product indicated by the appearance of only one set of dppz and bridgehead (NCHN) ${ }^{1} \mathrm{H}-\mathrm{NMR}$ resonances (Figure 3.3b) with the same chemical shifts as those labeled $\ddagger$ in Figure 3.2b.

X-ray crystallography confirmed the identity of $\mathbf{1 0}$ and will be discussed in the next section.

It is evident from Figure 3.3b that the resonances for the dppz ligands in $\mathbf{1 0}$ are shifted downfield as compared to those of the free ligand, but are positioned upfield relative to those of $c i s-\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3,4}(\mathrm{dppz})\right]\left[\mathrm{BF}_{4}\right]_{2}$ (labeled $\dagger$ in Figure 3.2). These shifts are similar to those reported for the free dppz ligand, cis-[ $\mathrm{Rh}_{2}(\mu-$ $\left.\left.\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})_{2}\right]^{2+}$, and cis- $\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})\left(\eta^{1}-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)\left(\mathrm{CH}_{3} \mathrm{OH}\right)\right]^{+} .{ }^{45-47}$

A slightly greater amount than two equivalents of dpq, dppz, dppn ligands were used in the reactions with cis- $\left[\mathrm{Rh}_{2}(\mathrm{~F} \text {-form })_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ combined with refluxing conditions to induce the full substitution of all four eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands by the diimine ligands. In general, the addition of excess diethyl ether to the $\mathrm{CH}_{3} \mathrm{CN}$ reaction mixture results in precipitation of the desired product along with an admixture of excess diimine ligand in some cases. In the latter instances, the pure products were obtained by recrystallization from slow diffusion of diethyl ether into the $\mathrm{CH}_{3} \mathrm{CN}$ solution.

The purity of compounds $\mathbf{9 - 1 4}$ was confirmed by ${ }^{1} \mathrm{H}$ NMR spectroscopy. Upon coordination of the diimine ligands to the $\mathrm{Rh}_{2}{ }^{4+}$ core, the characteristic triplet resonance of the bridgehead protons (NCHN) on the [DTolF] ligands typically shift to lower field as compared to that in cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ at 7.52 ppm , observed at 8.29 , 8.31 and 8.31 ppm in $\mathbf{9 - 1 1}$, respectively (Figure 3.3). Similarly, this triplet is observed at 7.49 ppm in cis-[ $\left[\mathrm{Rh}_{2}(\mathrm{~F} \text {-form })_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ as compared to $8.27,8.27$ and 8.28 ppm in 12-14, respectively (Figure 3.4). The resonance associated with the ax $\mathrm{CH}_{3} \mathrm{CN}$ ligands, is present at 1.96 ppm as free $\mathrm{CH}_{3} \mathrm{CN}$ due to the rapid exchange of them with $\mathrm{CD}_{3} \mathrm{CN}$

Figure 3.3 The aromatic region of the ${ }^{1} \mathrm{H}$ NMR spectra for $\mathbf{9 - 1 1}$ in $\mathrm{CD}_{3} \mathrm{CN}$.

Figure 3.4 The aromatic region of the ${ }^{1} \mathrm{H}$ NMR spectra for $\mathbf{1 2 - 1 4}$ in $\mathrm{CD}_{3} \mathrm{CN}$.
solvent molecules, as is typical for $\mathrm{Rh}_{2}$ (II,II) complexes. ${ }^{21}$ Only one set of resonances for the diimine ligands is observed in the ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{9 - 1 1}$ and $\mathbf{1 2 - 1 4}$, as illustrated in Figures 3.3 and 3.4 which supports the conclusion that the two diimine ligands are magnetically equivalent in each complex. The major species in the mass spectra of $\mathbf{9}, \mathbf{1 0}$ and $\mathbf{1 1}$ correspond to the intact $2^{+}$cationic unit of the parent compound with the correct isotope distribution.

## X-ray crystallography

cis $-\left[\mathbf{R h}_{2}(\mathbf{D T o l F})_{\mathbf{2}}(\mathbf{d p q})_{\mathbf{2}}\left(\mathbf{C H}_{\mathbf{3}} \mathbf{C N}\right)\right]\left[\mathbf{B F}_{4}\right]_{\mathbf{2}}$ (9). Compound 9 crystallizes in the space group of Pbca . Its molecular structure consists of a cationic dirhodium unit bridged by two $[\mathrm{DTolF}]^{-}$ligands in a cisoid disposition (Figure 3.5). Two outer-sphere $\left[\mathrm{BF}_{4}\right]^{-}$ anions are present as well. Each Rh (II) center is further chelated by a dpq ligand that occupies two eq positions (Figure 3.5). One of the two ax positions is occupied by a solvent acetonitrile molecule at a bond distance of 2.094(4) $\AA$. The occupation of only one axial site is not uncommon for dirhodium(II,II) compounds equipped with $[\mathrm{DTolF}]^{-}$ ligands and is attributed to its strong electron donating ability as well as the steric hindrance afforded by the bulky tolyl groups. The Rh-Rh bond distance is $2.5684(7) \AA$, which is comparable to that found in the related compounds cis$\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2},{ }^{104} \quad$ cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{bpy})\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}\right]\left[\mathrm{BF}_{4}\right]_{2}$, and cis$\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{bpy})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)\right]\left[\mathrm{BF}_{4}\right]_{2} .{ }^{129}$ The $\mathrm{Rh}-\mathrm{N}(\mathrm{dpq})$ bond distances are in a small range, from $2.029(4)$ to $2.064(4) \AA$. The two dpq ligands in the molecule adopted a staggered geometry to reduce the repulsion between them, with the dihedral angles defined by N5-Rh1-Rh2-N7 ~ 27.3(2) ${ }^{\circ}$.

Figure 3.5 Cationic unit of $\mathbf{9}$ drawn at $50 \%$ probability level.
cis $-\left[\mathbf{R h}_{2}(\mathbf{D T o l F})_{\mathbf{2}}(\mathbf{d p p z})_{\mathbf{2}}\left(\mathbf{C H}_{3} \mathbf{C N}\right)\right]\left[\mathbf{B F}_{4}\right]_{\mathbf{2}}(\mathbf{1 0})$. The molecular structure of $\mathbf{1 0}$ is similar to 9 , with a distance of $2.158(6) \AA$ for $\mathrm{Rh}-\mathrm{N}\left(\mathrm{ax} \mathrm{CH}_{3} \mathrm{CN}\right.$ ) bond. The $\mathrm{Rh}-\mathrm{Rh}$ bond distance is $2.597(1) \AA$, which is slightly longer than that was found in 9 . The Rh-N bond distances (dppz) range from $2.040(5)$ to $2.060(2) \AA$, longer than those reported for cis-$\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})_{2}\right]\left[\mathrm{O}_{2} \mathrm{CCH}_{3}\right]_{2} .{ }^{46}$ The longer Rh-diimine N bond in $\mathbf{1 0}$ is explained on the basis of a stronger trans influence induced by the more electron-rich [DTolF] ligand as compared to $\left[\mathrm{CH}_{3} \mathrm{CO}_{2}\right]^{-}$ligand.

The presence of the Rh-Rh single bond brings the two dppz ligands into close proximity, leading to the splay from a parallel alignment to reduce the steric repulsions. The twist angle of the two dppz ligands away from the eclipsed geometry is $15.6^{\circ}$, similar to the angle of $13^{\circ}$ in cis- $\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})_{2}\right]\left[\mathrm{O}_{2} \mathrm{CCH}_{3}\right]_{2}$. The view along the b axis of the crystal packing diagram of $\mathbf{1 0}$ (Figure 3.6b), reveals $\pi$-stacking interactions of the dppz ligands between two adjacent dirhodium cations along the c axis. Since these ligands are not parallel to each other, no definitive distances can be determined between the two planes defined by them, but it is noted that the distances between C43 and C46 and the plane defined by C43-C44-C45-C46-C47-C48 in the adjacent dppz ligands are 3.47 and $3.42 \AA$, respectively, as depicted in Figure 3.6b. Such short intermolecular distances are indicative of $\pi$-stacking interactions between the two adjacent molecules. The crystal packing diagrams of $\mathbf{1 0}$ viewed along the b and c axes are provided in Figure 3.6c and 3.6d respectively.

Figure 3.6 Crystal structure of $\mathbf{1 0}$ showing (a) thermal ellipsoid plot of the cation drawn at $50 \%$ probability level and (b) the crystal packing of the cations showing intermolecular $\pi$-stacking; the $\left[\mathrm{BF}_{4}\right]^{-}$anions and hydrogen atoms are omitted for the sake of clarity.
cis $\left.-\left[\mathbf{R h}_{2}(\mathbf{D T o l F})_{2}(\mathbf{d p p n})_{2}\right) \mathrm{Cl}\right]\left[\mathrm{BF}_{4}\right] \cdot \mathrm{Et}_{\mathbf{2}} \mathrm{O} \cdot \mathbf{3} \mathrm{CH}_{3} \mathbf{C N}\left(\mathbf{3} \cdot \mathbf{E t}_{2} \mathbf{O} \cdot \mathbf{3} \mathbf{C H}_{3} \mathbf{C N}\right)$. The cation in complex $\mathbf{1 1}$ crystallizes in the space group $P-1$ along with one $\left[\mathrm{BF}_{4}\right]^{-}$as well as three acetonitrile and one diethyl ether interstitial solvent molecules. The coordination sphere of the $\mathrm{Rh}(\mathrm{II})$ centers is similar to that found in $\mathbf{1 0}$ except that one ax position is occupied by a $\mathrm{Cl}^{-}$ligand (Figure 3.7a). The $\mathrm{Rh}-\mathrm{Cl}$ distance of $2.4562(7) \AA$ is comparable to that reported for $\left[\mathrm{Rh}_{2}(1,3 \text {-diisocyanopropane })_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}_{2}$, in which $\mathrm{Rh}-\mathrm{Cl}$ (ax) is $2.4472(8) \AA,{ }^{159}$ but is significantly longer than the Rh-N (ax $\mathrm{CH}_{3} \mathrm{CN}$ ) bond length in $\mathbf{1 0}$, which is not surprising given the larger size of the $\mathrm{Cl}^{-}$ion. The Rh-Rh bond distance is 2.5818(3) $\AA$ and the Rh-N (dppn) bond distances range from 2.032(2) to 2.053(3) $\AA$, comparable the corresponding metrical parameters found in 9 and 10. The two dppn ligands are twisted away from the eclipsed configuration with a dihedral angle of $\sim 28^{\circ}$. This value is significantly larger than was found for the dppz ligands in 10, indicating the stronger repulsions between the two adjacent dppn ligands in $\mathbf{1 1}$.
cis $\left.-\left[\mathbf{R h}_{2}(\mathbf{F}-\text { form })_{2}(\mathbf{d p q})_{2}\left(\mathbf{C H}_{3} \mathbf{C N}\right)_{2}\right)\right]\left[\mathrm{BF}_{4}\right]_{\mathbf{2}}(\mathbf{1 2})$. The molecular structure of the cationic unit of $\mathbf{1 2}$ depicted in Figure 3.7 b is similar to that of $\mathbf{1 0}$, but with both ax positions being occupied by $\mathrm{CH}_{3} \mathrm{CN}$ ligands as a result of the smaller size and less electron-rich nature of the $[\mathrm{F}-\text { form }]^{-}$vs. the $[\mathrm{DTolF}]^{-}$ligands. The Rh-Rh distance is 2.599(1) $\AA$ and the $\mathrm{Rh}-\mathrm{N}$ ([F-form] $]^{-}$) distances range from $2.034(5)$ to $2.052(5) \AA$, similar to that found in cis-[ $\left.\mathrm{Rh}_{2}(\mathrm{~F} \text {-form })_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$. The Rh-N $(\mathrm{dpq})$ distances are in the range of $2.035(3)-2.053(3) \AA$, similar to the Rh-N (dppz) lengths in 10. The internal twist angles away from the eclipsed geometry of the two dpq ligands defined by N5-Rh1-Rh2-N7 and N6-Rh1-Rh2-N8 are $-18.6(1)^{\circ}$ and $-18.9(1)^{\circ}$.

Figure 3.7 Thermal ellipsoid plot of (a) $\mathbf{1 1}$ an (b) $\mathbf{1 2}$ drawn at the $50 \%$ probability level; hydrogen atoms, $\left[\mathrm{BF}_{4}\right]^{-}$anion, and interstitial solvent molecules are omitted for the sake of clarity.

Figure 3.8 Thermal ellipsoid plots drawn at the $50 \%$ probability level; the anions, hydrogen atoms and interstitial solvent molecules are omitted for the sake of clarity (a) 13 (b) 14.
cis-[ $\left.\mathbf{R h}_{\mathbf{2}}(\mathbf{F} \text {-form })_{\mathbf{2}}(\mathbf{d p p z})_{\mathbf{2}}\left(\mathbf{C H}_{3} \mathbf{C N}\right)_{2}\right]\left[\mathbf{B F}_{4}\right]_{2}$ (13). Compound $\mathbf{1 3}$ crystallizes in the $P-1$ space group. The thermal ellipsoid plot of the cationic unit is shown in Figure 3.8a. Both ax positions of $\mathbf{1 3}$ are occupied by solvent $\mathrm{CH}_{3} \mathrm{CN}$ molecules with the distances of 2.210(6) and 2.256(6) $\AA$. The Rh-Rh bond distance of 2.6190(9) $\AA$ is slightly longer than the corresponding distances in 12. The Rh-N ([F-form] $]^{-}$) bond distances are in the range 2.043(5)-2.065(5) $\AA$, similar to those found in 12. The Rh-N (dppz) bond distances are $\sim 2.06 \AA$, similar to those in $\mathbf{1 0}$. The two dppz ligands in one molecule of $\mathbf{1 3}$ are twisted away from the eclipsed configuration with dihedral angles of $16.8(2)^{\circ}$ (defined by N7-Rh2-Rh1-N5).
 the dirhodium cations in $\mathbf{1 2}$ and $\mathbf{1 3}$, both ax positions are occupied by $\mathrm{CH}_{3} \mathrm{CN}$ ligands in 14 with bond distances of $2.202(7)$ and $2.245(9) \AA$ (Figure $3.8 b$ ). The Rh-Rh bond distance is $2.614(1) \AA$, slightly longer than those found in $\mathbf{1 2}$ but comparable to that in 13. The Rh-N ([F-form $]^{-}$) bond distances are in the range 2.047(5)-2.069(4) $\AA$, similar to that for $\mathbf{1 2}$ and 13. The Rh-N (dppn) bond distances range from 2.042(8) to 2.064(6) $\AA$, comparable to those in 12. Much larger distortions between the two diimine ligands is evident in $\mathbf{1 4}$ as compared to that of $\mathbf{1 2}$ and $\mathbf{1 3}$, with the angles defined by N5-Rh1-Rh2N7 and N6-Rh1-Rh2-N8 being $-21.7(2)^{\circ}$ and $-21.8(2)^{\circ}$ respectively, due to considerable repulsion between the two dppn ligands.

The detailed crystal refinement parameters are listed in Table 3.1 whereas the bond distances and dihedral angles are compiled in Table 3.2

## Electronic absorption and electrochemistry

Data regarding the photophysical properties of $\mathbf{9 - 1 4}$ in $\mathrm{CH}_{3} \mathrm{CN}$ are compiled in Table 3.3. The relatively distinct transitions in the region between 280 and 420 nm for all the complexes are attributed to the intramolecular ${ }^{1} \pi \pi^{*}$ electronic transitions resulting from the free diimine ligands; e.g. the dpq ligand absorbs at $254 \mathrm{~nm}\left(\varepsilon=53,000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ in $\mathrm{CHCl}_{3}$, comparing well with the maxima of $\mathbf{9}$ and $\mathbf{1 2}$ at $289 \mathrm{~nm}\left(\varepsilon=54,000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ and $291 \mathrm{~nm}\left(\varepsilon=50,000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$, respectively. Similarly, the dppz and dppn ligands exhibit absorption maxima at $370 \mathrm{~nm}\left(\varepsilon=17,200 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ and $414 \mathrm{~nm}\left(\varepsilon=12,500 \mathrm{M}^{-}\right.$ ${ }^{1} \mathrm{~cm}^{-1}$ ) respectively in $\mathrm{CHCl}_{3},{ }^{36}$ similar to those measured for $\mathbf{1 0}$ and $\mathbf{1 3}(\sim 370 \mathrm{~nm})$ and 11 and $14(\sim 418 \mathrm{~nm})$, respectively (Table 3.3). It is also noted that these transitions are also observed in the related complexes cis- $\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{~L})\left(\eta^{1}-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)\left(\mathrm{CH}_{3} \mathrm{OH}\right]^{+}\right.$ $(\mathrm{L}=\mathrm{dpq}, \quad \mathrm{dppz}, \quad \mathrm{dppn}), \quad c i s-\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})_{2}\right]^{2+}, \quad c i s-\left[\mathrm{Rh}_{2}(\mu-\right.$ $\left.\left.\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppn})_{2}\right]^{2+},{ }^{44-48}$ as well as in $\mathrm{Ru}(\mathrm{II})$ and $\mathrm{Os}(\mathrm{II})$ complexes containing dpq, dppz, and dppn ligands. ${ }^{36,37,160-163}$ More intense bands are observed at higher energies in the 250-280 nm rage, namely 256 nm for $\mathbf{9}$ and $\mathbf{1 2}, 275 \mathrm{~nm}$ for $\mathbf{1 0}$ and $\mathbf{1 3}$, and 261 nm for 11 and 14. Although a small dependence is apparent as a function of the diimine ligands, it is likely that these are metal-centered transitions involving orbitals participating in bonding interactions with the diimine ligands. Similar transitions are also observed in $\mathrm{Rh}_{2}$ (F-form $)_{4}$ at $230 \mathrm{~nm}\left(\varepsilon=42,000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ and $275 \mathrm{~nm}\left(\varepsilon=23,900 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ and in $\mathrm{Rh}_{2}(\mathrm{DTolF})_{4}$ at $265 \mathrm{~nm}\left(\varepsilon=61,800 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ in $\mathrm{CH}_{3} \mathrm{CN}$.

${ }^{a}$ vs. $\mathrm{Ag} / \mathrm{AgCl} ; 0.1 \mathrm{M}\left[\mathrm{n}-\mathrm{Bu}_{4} \mathrm{~N}\right]\left[\mathrm{PF}_{6}\right] ; 0.2 \mathrm{~V} / \mathrm{s} .{ }^{b}$ Quasi reversible. ${ }^{c}$ Irreversible.

Figure 3.9 Electronic absorption spectra of $\mathbf{9}$ and $\mathbf{1 2}$ (left), $\mathbf{1 0}$ and $\mathbf{1 3}$ (middle), and $\mathbf{1 1}$ and 14 (right) in $\mathrm{CH}_{3} \mathrm{CN}$.

In addition to the higher energy transitions there is a tail in the absorption profile for each complex that extends to lower energies as listed in Table 3.3 and illustrated in Figure 3.9. The dependence of the absorption maxima on the identity of the diimine ligands as well as the bridging formamidinate ligands for each series taken together with the intensities being in the $\sim 1-3 \times 10^{3} \mathrm{M}^{-1} \mathrm{~cm}^{-1}$, points to the assignment of these lower energy bands as charge-transfer transitions from the formamidinate to the diimine ligands. Such charge-transfer features are also observed in the related cis-[ $\mathrm{Rh}_{2}(\mu-$ $\left.\left.\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{~L})_{2}\right]^{2+}$ complexes where L is dpq, dppz and dppn with maxima in the range $609-620 \mathrm{~nm}$ with similar intensities $\left(\varepsilon=1,100-3,800 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right) .{ }^{48}$ The increased electron donation from the formamidinate ligands to the bimetallic core as compared to acetate is consistent with the lower energies of these charge-transfer transitions in 9-11 and 12-14. In addition, these transitions are observed at lower energies for the [DTolF] complexes as compared to the corresponding [F-form] ${ }^{-}$compounds, which is in accord with that the formamidinate ligands participate in the transition.

The observed redox couples measured for 9-11 and 12-14 are compiled in Table 3.3. A redox couple is observed at approximately -0.4 V vs. $\mathrm{Ag} / \mathrm{AgCl}$ in $\mathbf{9 - 1 1}$ and $\mathbf{1 2 - 1 4}$ (Table 3.3, Figure 3.10 for complex 13). This process represents oxidation of the complexes which has been confirmed by a color change observed in the presence of oxidizing agents such as TCNQ, 7,7,8,8-tetracyanoquinonedimethane, $\left(\mathrm{E}^{\prime}=-0.14\right.$ vs. SCE in $\left.\mathrm{CH}_{3} \mathrm{CN}, \Delta \mathrm{G}=-0.30 \mathrm{~V}\right), \mathrm{AgBF}_{4}$ in $\mathrm{CH}_{3} \mathrm{CN}\left(\mathrm{E}^{\prime}=+0.44 \mathrm{~V} v s . \mathrm{SCE}, \Delta \mathrm{G}=-0.88\right.$ $\mathrm{V})$ and $\mathrm{NOBF}_{4}\left(\mathrm{E}^{\prime}=+1.03 \mathrm{~V}\right.$ vs. $\left.\mathrm{SCE}, \Delta \mathrm{G}=-1.47 \mathrm{~V}\right) .{ }^{164}$ Following the oxidation of 9 and $\mathbf{1 0}$ with TCNQ, an IR stretch at $\sim 2186 \mathrm{~cm}^{-1}$ is observed which is known to
correspond to the TCNQ radical anion, TCNQ ${ }^{-} .{ }^{165}$ The product of the reaction of $\mathbf{1 0}$ with $\mathrm{NOBF}_{4}$ was isolated; the absorption spectrum is shown in Figure 3.11. The facile oxidation of these dirhodium(II,II) complexes is not unexpected given the presence of the electron-rich formamidinate ligands.

The second oxidation process is at $\sim+1.06 \mathrm{~V}$ vs. $\mathrm{Ag} / \mathrm{AgCl}$ for the $[\mathrm{DTolF}]^{-}$ complexes $\mathbf{9 - 1 1}$ and $\sim+1.17 \mathrm{~V}$ vs. $\mathrm{Ag} / \mathrm{AgCl}$ for the $\left[\mathrm{F}\right.$-form] ${ }^{-}$series $\mathbf{1 2 - 1 4}$ (Table 3.3). This couple is reversible in the case of $\mathbf{9}$ and quasi-reversible for 10-11, and 12-14 and is independent of the nature of the diimine ligand in each series but dependent on the substituents on the formamidinate ligand. As expected, the complexes with $[\mathrm{DTolF}]^{-}$ ligands are more easily oxidized than those containing the electron withdrawing fluoride substituents, viz., $[\mathrm{F}-\text { form }]^{-}$(Table 3.3). The difference of $\sim 0.1 \mathrm{~V}$ for the [DTolF] $^{-}$and

Figure 3.10 Cyclic voltammogram (top) and differential pulse voltammogram (bottom) of complex $\mathbf{1 3}$ in $\sim 0.1 \mathrm{M}\left[\mathrm{n}-\mathrm{Bu}_{4} \mathrm{~N}\right]\left[\mathrm{PF}_{6}\right] \mathrm{CH}_{3} \mathrm{CN}$ solution at room temperature.

Figure 3.11 Comparison of the electronic absorption spectra of [9] ${ }^{+}$and 9 (left) and of [10] ${ }^{+}$and $\mathbf{1 0}$ (right) in $\mathrm{CH}_{3} \mathrm{CN}$.
[F-form] complexes is similar to the difference in the second oxidation potentials of $\mathrm{Rh}_{2}(\mathrm{DTolF})_{4}$ and $\mathrm{Rh}_{2}(\mathrm{~F} \text {-form })_{4}$ of 0.14 V ; the $\mathrm{E}_{1 / 2}$ values are +0.85 V and +0.99 V vs. SCE, respectively. ${ }^{143}$ The third oxidation process is irreversible for all the complexes with $\mathrm{E}_{\mathrm{pa}} \sim+1.6 \mathrm{~V}$ vs. $\mathrm{Ag} / \mathrm{AgCl}$ for $\mathbf{9 - 1 1}$ and $\sim+1.7 \mathrm{~V}$ vs. $\mathrm{Ag} / \mathrm{AgCl}$ for $\mathbf{1 2 - 1 4}$ (Table 3.3). The 0.1 V difference between the two series is consistent with this oxidation correspondent to the removal of one electron from orbital with significant formamidinate character.

The first reduction occurs at $-1.03 \mathrm{~V},-0.94 \mathrm{~V}$, and $-0.67 \mathrm{~V} v . \mathrm{Ag} / \mathrm{AgCl}$ for $\mathbf{9}, \mathbf{1 0}$, and $\mathbf{1 1}$ (Table 3.3), respectively, and is clearly dependent on the nature of the diimine ligand. These values are similar to those found for the corresponding [F-form] ${ }^{-}$ complexes 12, 13, and 14, at $-0.98,-0.91$, and $-0.61 \mathrm{vs} . \mathrm{Ag} / \mathrm{AgCl}$ (Table 3.3). The trends for each series of complexes, considering the fact that the diimine ligand L is easier to reduce in the order dppn $>\mathrm{dppz}>\mathrm{dpq}$, is consistent with the first reduction being centered on this ligand. These values are also comparable to those reported for
$\mathrm{Ru}(\mathrm{II})$ complexes with dpq, dppz, and dppn ligands. ${ }^{166}$ The potential of the second reduction process is also dependent on the diimine ligand L (Table 3.3 ), which is also the case for $\mathrm{Ru}(\mathrm{II})$ complexes, and may be assigned to the placement of an electron on the remaining neutral diimine ligand. A third reduction process is observed in the range of 1.39 to -1.55 V vs. $\mathrm{Ag} / \mathrm{AgCl}$ for $\mathbf{9 - 1 1}$ and $\mathbf{1 2 - 1 4}$, in accord with a metal-centered reduction. On the basis of the typical electronic structure of $d^{7}-d^{7}$ paddlewheel complexes, it is reasonable to expect that the third reduction corresponds to the population of the $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbital. ${ }^{21}$ These values are similar to the corresponding data for $\mathrm{Rh}_{2}(\mathrm{DTolF})_{4}$ at $-1.23 \mathrm{~V} v s$. $\mathrm{Ag} / \mathrm{AgCl}$ that do not possess diimine ligands. ${ }^{143}$

## Electronic structure calculations

Computational studies of the $[\mathrm{DTolF}]^{-}$and $\left[\mathrm{F}-\right.$ form] ${ }^{-}$series of compounds were performed in order to gain a deeper understanding of their electronic structures. Geometric parameters for the gas phase optimizations were obtained from the crystal structures. For the calculations of $\mathbf{9 - 1 1}$, two $\mathrm{CH}_{3} \mathrm{CN}$ ligands were placed in both ax positions given that only one set of dpq, dppz and dppn resonances was observed in the solution ${ }^{1} \mathrm{H}$ NMR spectra, indicating a symmetrical coordination environment. The calculated structures of $\mathbf{1 2 - 1 4}$ are depicted in Figure 3.12.

The calculated MO diagrams of $\mathbf{9 - 1 1}$ and $\mathbf{1 2 - 1 4}$ are shown in Figure 3.13, and the contributions to the orbitals from the metal and the ligands are listed in Tables 3.4 and 3.5.

The HOMO and HOMO-1 are of all the complexes are calculated to contain significant contributions from the formamidinate ligands. In general, the HOMO of each complex exhibits $\sim 63 \%$ contribution from the $[D T o l F] ~^{-}$or $[F-f o r m]^{-}$ligand and $\sim 33 \%$ from Rh , whereas the HOMO-1 typically contains $\sim 84 \%$ formamidinate and $\sim 10 \% \mathrm{Rh}$ character (Tables 3.4 and 3.5). Consistent with the ligand contributions to these orbitals, the relative energy of the HOMO and HOMO-1 vary with the nature of the formamidinate ligand by $\sim 0.1 \mathrm{eV}$. The HOMO-2 has $\sim 65 \%$ [DTolF] and $30 \% \mathrm{Rh}$ contributions in $\mathbf{9}$ and 10, but this orbital is metal-centered in $\mathbf{1 2}$ and $\mathbf{1 3}$, with $79 \% \mathrm{Rh}_{2}(\sigma)$ character and $9 \%$ contribution from the ax $\mathrm{CH}_{3} \mathrm{CN}$ ligands. In the dppn complexes $\mathbf{1 1}$ and $\mathbf{1 4}$, however, the HOMO-2 is completely localized on the dppn ligand.

It is evident from Tables 3.4 and 3.5 that the LUMO to LUMO+5 orbitals in $\mathbf{9 - 1 4}$ are centered on the corresponding diimine ligand. The relative energies of the LUMOs are consistent with the ease of reduction of the complexes, i.e., $\mathbf{9}$ and $\mathbf{1 2}$ are more difficult to reduce than $\mathbf{1 0}$ and 13, and $\mathbf{1 1}$ and $\mathbf{1 4}$ are easier to reduce (Table 3.3). In each complex, the LUMO+6 is calculated to possess $66 \% \mathrm{Rh}_{2}\left(\sigma^{*}\right)$ character with $15 \%$ contribution from ax $\mathrm{CH}_{3} \mathrm{CN}$ ligands. The HOMO, LUMO and LUMO+6 levels of $\mathbf{9}$ are depicted in Figure 3.14 and are representative of the ones calculated for $\mathbf{1 0}, \mathbf{1 1}$, and 12-14.

Figure 3.14 Electron density maps of the HOMO, LUMO and LUMO+6 of 9 drawn with iso-value $=0.04$.

The vertical energies and orbital contributions for the lowest eight singlet excited states of $\mathbf{9 - 1 1}$ and 12-14 are listed in Tables 3.6 and 3.7, respectively. In all complexes, the major contribution to the lowest energy singlet excited state ( $\geq 82 \%$ in $\mathbf{9 - 1 1}$ and $\geq 78 \%$ in 12-14) corresponds to the transfer of electron density from the HOMO to the LUMO of each complex. Because the HOMO exhibits a high degree of formamidinate character ( $\sim 66 \%$ ) and the LUMO is localized on the corresponding diimine ligands, this state may be assigned as a ligand-to-ligand charge transfer $\left({ }^{1}\right.$ LLCT). The calculated oscillator strengths, $f$, of the vertical transitions from the ground state, ${ }^{1} \mathrm{GS}$, to the lowest energy state, ${ }^{1}$ LLCT state listed in Tables 3.6 and 3.7 are relatively low in $\mathbf{9}(f=0.0014), \mathbf{1 0}(f$ $=0.0004), \mathbf{1 2}(f=0.0012)$, and $\mathbf{1 3}(f=0.0004)$, but the calculated transition energies are in good agreement with the experimental maxima in these complexes (Table 3.3). For example, the calculated energy of the ${ }^{1}$ GS $\rightarrow{ }^{1}$ LLCT transitions in $\mathbf{9}$ and $\mathbf{1 2}$ are 536 nm and 518 nm , which compare well with the estimated experimental maxima of 525 nm

Table 3.6 Vertical energies of the singlet excited states, $\lambda$ (in nm), oscillator strengths, $f$, and major orbital contributions ${ }^{a}$ calculated for $\mathbf{9 - 1 1}$ in $\mathrm{CH}_{3} \mathrm{CN}(\mathrm{H}=\mathrm{HOMO} ; \mathrm{L}=\mathrm{LUMO}$ ).

|  |  |  | $\mathrm{H}-2 \rightarrow \mathrm{~L}(26.9 \%)$ |

${ }^{a}$ Only contributions of $\geq 20 \%$ are listed.
and 520 nm , respectively (Table 3.3 and Figure 3.9a). We also note that the only other transitions calculated with a greater oscillator strength in the visible region are those at $457 \mathrm{~nm}(f=0.0015), 446 \mathrm{~nm}(f=0.013)$ and $438 \mathrm{~nm}(f=0.0022)$ for 9 and $459 \mathrm{~nm}(f$ $=0.0016), 447 \mathrm{~nm}(f=0.0047)$, and $427 \mathrm{~nm}(f=0.0091)$ for 12. These calculated values are consistent with the increasing intensity of the absorption at $\lambda<500 \mathrm{~nm}$, but, because these are shoulders, it is difficult to estimate an experimental maxima.

The calculated maxima for the lowest energy ${ }^{1} \mathrm{GS} \rightarrow{ }^{1}$ LLCT transitions at 562 nm and 537 nm for $\mathbf{1 0}$ and 13, respectively, are bathochromic shifted from those of $\mathbf{9}$ and $\mathbf{1 2}$ (Tables 3.6 and 3.7), consistent with ease of reduction for the diimine ligands in the former as compared to the latter compounds (Table 3.3). This trend is also observed in the maxima of the lowest energy transitions of $\mathbf{1 0}$ and $\mathbf{1 3}$ at 541 nm and 537 nm , respectively, which compare well with the calculated values. In addition to the lowest energy transition, absorptions are also predicted to occur between 447 nm and 518 nm for $\mathbf{1 0}$, the strongest of which is at $470 \mathrm{~nm}(f=0.0108)$, listed in Table 3.6. Similarly, transitions at $497 \mathrm{~nm}(f=0.0010), 460 \mathrm{~nm}(f=0.0021)$, and $451 \mathrm{~nm}(f=0.0122)$ are calculated for $\mathbf{1 3}$ (Table 3.7).

A value of $f=0.0000$ is calculated for the ${ }^{1} \mathrm{GS} \rightarrow{ }^{1}$ LLCT lowest energy transitions of 11 and 14 at 611 nm and 579 nm , respectively (Tables 3.6 and 3.7); accordingly these transitions are not expected to have significant intensity. It should be noted, however, that the absorption spectrum of $\mathbf{1 1}$ (Figure 3.9) extends beyond 600 nm whereas that of 14 does not (Figure 3.9), a trend that is consistent with the calculated values. Other stronger electronic transitions are predicted at $523 \mathrm{~nm}(f=0.0022)$ and $515 \mathrm{~nm}(f=$
$0.0275)$ for 11 and $517(f=0.0287)$ for $\mathbf{1 4}$ which are consistent with the estimated maxima of the shoulders at $\sim 553 \mathrm{~nm}$ and $\sim 525 \mathrm{~nm}$ for 11 and 14, respectively (Table 3.3). The low energy transitions of $\mathbf{1 1}$ are red-shifted relative to those of $\mathbf{1 4}$, which is rationalized by the fact that $\left[\mathrm{DTolF}^{-}\right.$is a better electron donor than is [ F -form ${ }^{-}$which influences the transitions that involves depletion of electron density from the formamidinate ligands (Tables 3.6 and 3.7).

## Concluding remarks

The two series of dirhodium complexes in this chapter exhibit unusual photophysical properties involving low energy Ligand-to-Ligand Charge Transfer (LL'CT) transitions. This conclusion was confirmed by both experimental and theoretical data. The oxidation of these complexes is facile, as evidenced by their cyclic voltammetric diagrams. This is also in accord with the results of a series of chemical oxidation experiments. The data obtained in this project indicate that electronic properties tuning of dirhodium complexes can be readily achieved by a systematic ligand design approach.

## CHAPTER IV

## STUDY OF PARTIAL PADDLEWHEEL DIRHODIUM COMPLEXES WITH PYRIDINATE BRIDGING LIGANDS

## Introduction

The serendipitous discovery of the anticancer activity of cisplatin $\left(\right.$ cis $\left.-\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right)$ launched a new era of metals in medicinal research ${ }^{167,168}$ which was approved officially by the FDA in 1978 for the treatment of testicular and ovarian cancers. It has been well documented that the complex undergoes hydrolysis upon administration to generate the active aqua species cis- $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]^{+}$and cis- $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2+}$, which preferentially bind to the N-7 guanine site in DNA to form 1,2-intrastrand crosslinks. ${ }^{169-}$ ${ }^{180}$ These lesions induce DNA distortions, inhibit transcription and the DNA replication process and ultimately lead to the cell death. ${ }^{169-180}$ In spite of the efficacy of the drug, severe nephrotoxicity as well as intrinsic and acquired resistance ${ }^{181-186}$ have necessitated the development of second and third generation platinum-based anticancer drugs. During the past three decades, only two other platinum drugs, namely carboplatin ${ }^{187,188}$ and oxaliplatin, ${ }^{189,190}$ were approved for clinical use by the FDA in addition to several other platinum based drugs being approved in other countries. ${ }^{191}$ Considering the fact that platinum-based anticancer agents are highly effective and are the leading drugs for the current cancer therapy, there is a pressing need for new platinum-containing anticancer agents. ${ }^{192-205}$ Despite the efficacy of platinum anticancer drugs, other transition metal containing complexes also deserve further exploration, e.g. various dirhodium(II,II)
compounds that are active towards cisplatin-resistant cancer cell lines as well as some anticancer active complexes that are operative in different modes from cisplatin. ${ }^{3-7,10}$

Photodynamic Therapy (PDT) has emerged as a promising treatment for cancer as well as some other diseases with the advantage over conventional chemotherapy being that active toxic species are generated only in selectively irradiated tissues. The clinically approved drug for PDT treatment, Photofrin ${ }^{\circledR}$, functions by the production of reactive oxygen species including ${ }^{1} \mathrm{O}_{2}$ (singlet oxygen) upon irradiation with visible light $(\sim 630 \mathrm{~nm}) .{ }^{206}$ These cytotoxic species damage subcellular organelles and macromolecules, leading to apoptosis and/or necrosis of the affected cells. ${ }^{206}$ The low concentration of $\mathrm{O}_{2}$ or the slow diffusion of $\mathrm{O}_{2}$ from adjacent tissues, however, restricts the use of these drugs in dense hypoxic tumors. ${ }^{207-209}$ A different approach to the same problem can be to use transition metal complexes which can also produce ${ }^{1} \mathrm{O}_{2}$ but which can also bind covalently to relevant biomolecules upon irradiation due to the dissociation of photo-labile ligands in the excited states via an $\mathrm{O}_{2}$ independent pathway. ${ }^{210-219}$ Moreover, biologically active molecules can be attached to the metal complexes as the photo-labile ligands which, when released upon irradiation, will generate two active species, namely a metal complex with an open coordination site and an organic drug, from a single precursor. ${ }^{220-222}$

A recent study by the Turro group revealed the potential of the partial paddlewheel dirhodium(II,II) compound cis- $\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ as a PDT agent (Scheme 4.1). It is postulated that the photo-lability of the stable eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands in the dark is crucial for the formation of the active species upon light irradiation. ${ }^{9}$ As such,
different dirhodium(II,II) complexes with photo-labile $\mathrm{CH}_{3} \mathrm{CN}$ ligands were jointly developed by our research groups, e.g. head to head (H-H), head to tail (H-T) cis$\left[\mathrm{Rh}_{2}\left(\mathrm{NHOCCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}{ }^{223}$ and unbridged $\left[\mathrm{Rh}_{2}(\mathrm{phen})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{4}$ (phen: 1,10-phenanthroline) ${ }^{224}$ and found to have promising potential as effective PDT anticancer agents. To construct a structure/activity relationship for the dirhodium(II,II) partial paddlewheel complex with monodentate $\mathrm{CH}_{3} \mathrm{CN}$ ligands, the substituted oxopyridine (Scheme 4.1b) ligands were chosen as bridging ligands in the current study due to the easy tuning of the ligand field in these complexes. The results in this chapter involve the syntheses and characterization of series of dirhodium(II,II) complexes featuring two cis 6-R-oxo-pyridinate $\left(\mathrm{R}=-\mathrm{CH}_{3}\right.$, 6-methyl-oxo-pyridine, $\mathbf{m h p} ; \mathrm{R}=-\mathrm{Cl}$, 6-chloro-oxo-pyridine, chp; $\mathrm{R}=-\mathrm{F}$, 6-fluoro-oxo-pyridine, fhp.) bridging ligands; the investigation of their potential as PDT agents is also presented.

## Experimental section

## Starting materials

The compound $\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4} \bullet 2 \mathrm{CH}_{3} \mathrm{OH}$ was either purchased from Pressure Chemical Company or synthesized from $\mathrm{RhCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ as reported. ${ }^{225}$ The ligands 2-hydoxy-6methylpyridine (Hmhp), 2-hydroxy-6-chloropyridine (Hchp) were purchased from Sigma Aldrich and used as received whereas 2-hydroxy-6-fluoropyridine was purchased from VWR and used without further purification. The reagent $\mathrm{Et}_{3} \mathrm{OBF}_{4}\left(1 \mathrm{Min} \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ was purchased from Sigma Aldrich. The solvents acetonitrile, dichloromethane, diethyl ether, chlorobenzene, dimethyl sulfoxide (DMSO) and tetrahydrofuran (THF) were of ACS grade and used as received. The NMR solvents $\mathrm{D}_{2} \mathrm{O}\left(d_{2}\right)$ and $\mathrm{CD}_{3} \mathrm{CN}\left(d_{3}\right)$ were purchased from Cambridge Isotope Laboratory. The compound $\mathrm{Rh}_{2}(\mathrm{mhp})_{4}$ (15) was synthesized according to a slightly modified literature procedure. ${ }^{226}$

Preparation of $\left.\mathbf{R h}_{\mathbf{2}} \mathbf{( c h p}\right)_{\mathbf{4}} \mathbf{( 1 6 )}$. A quantity of $\sim 4.4$ equivalents of Hchp ligand ( 220 mg , 1.70 mmol ) was mixed with 50 mL of chlorobenzene suspended with $\mathrm{Rh}_{2}(\mu-$ $\left.\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4} \cdot 2 \mathrm{CH}_{3} \mathrm{OH}(195 \mathrm{mg}, 0.39 \mathrm{mmol})$ and refluxed for 36 h , forming a slightly green colored solution with a large quantity of yellow precipitate. The solid was collected by filtration and then washed with copious volumes of $\mathrm{CH}_{3} \mathrm{OH}(50 \mathrm{~mL})$ to remove unreacted Hchp ligand. The yield is 235 mg , which is $85 \%$ based on rhodium.

Preparation of $\mathbf{R h}_{\mathbf{2}}(\mathbf{f h p})_{\mathbf{4}}(\mathbf{1 7})$. A quantity of $\sim 4.1$ equivalents of Hfhp ligand ( 186 mg , $1.65 \mathrm{mmol})$ was mixed with a suspension of $\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4} \cdot 2 \mathrm{CH}_{3} \mathrm{OH}(200 \mathrm{mg}, 0.40$ mmol ) in 50 mL of chlorobenzene and refluxed for 48 h . The resulting teal colored solution which contained a large amount of green precipitate was dried under vacuum
after which time 50 mL CH 3 OH was added and the solution was filtered through a medium frit to remove unreacted Hfhp ligand. The product was collected as a green solid ( $240 \mathrm{mg}, 93 \%$ yield). Crystals suitable for X-ray diffraction were obtained from slow evaporation of an acetone solution containing the product in the presence of several drops of DMSO. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO} \sim d_{6}\right): 7.29$ (m, fhp), 6.22 (d, fhp), 6.09(d, fhp).

Preparation of cis- $\left[\mathbf{R h}_{\mathbf{2}}(\mathbf{m h p})_{\mathbf{2}}\left(\mathbf{C H}_{\mathbf{3}} \mathbf{C N}\right)_{6}\right]\left[\mathbf{B F}_{4}\right]_{2}(\mathbf{1 8})$. An amount of $\mathrm{Rh}_{2}(\mathrm{mhp})_{4}(81 \mathrm{mg}$,
 of 0.5 mL of $\mathrm{Et}_{3} \mathrm{OBF}_{4}\left(1.0 \mathrm{M}\right.$ in $\left.\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ was added to this suspension, leading to instantaneous formation of a clear green solution which eventually turned into red color over the course of 6 hours. The solution was stirred at room temperature for 24 h and then concentrated to 5 mL and treated with 50 mL of diethyl ether which led to the precipitation of the product in an oily form. The oil was washed with copious quantities of diethyl ether and recrystallized by slow diffusion of diethyl ether into the $\mathrm{CH}_{3} \mathrm{CN}$ solution of the product at room temperature. The yield is 82 mg ( $75 \%$ based on rhodium). X-ray quality crystals were obtained in a similar fashion. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}-d_{3}\right) \delta$ ppm: 7.21 (t, 2H, mhp), 6.36 (d, 2H, mhp), 6.22 (d, 2H, mhp), 2.63 (s, $6 \mathrm{H},-\mathrm{CH}_{3}$ of mhp), 2.47 ( $\mathrm{s}, 6 \mathrm{H}$, eq $\mathrm{CH}_{3} \mathrm{CN}$ ), 2.46 ( $\mathrm{s}, 6 \mathrm{H}$, eq $\mathrm{CH}_{3} \mathrm{CN}$ ).

Preparation of H-T (19) and H-H (20) cis-[Rh $\left.\mathbf{R}_{2}(\mathbf{c h p})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$. An amount of $\mathrm{Rh}_{2}(\mathrm{chp})_{4}(90.4 \mathrm{mg}, 0.13 \mathrm{mmol})$ was suspended in 30 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{CH}_{3} \mathrm{CN}(\mathrm{v}: \mathrm{v}=1: 2)$ and a 0.4 mL aliquot of $\mathrm{Et}_{3} \mathrm{OBF}_{4}\left(1 \mathrm{M}\right.$ in $\left.\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ was then added to the flask. The solution gradually became clear over the course of the next 6 h and was then stirred at room temperature for a total of 28 h . The solution eventually became clear red and was
concentrated to 5 mL and treated with 80 mL of diethyl ether, which led to the formation of an oily residue which was washed with copious diethyl ether to obtain a red powder ( 98 mg ). As evidenced by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy, this solid contains both $\mathrm{H}-\mathrm{H}$ and $\mathrm{H}-\mathrm{T}$ isomers of cis- $\left[\mathrm{Rh}_{2}(\mathrm{chp})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$. The material was redissolved in 5 mL of $\mathrm{CH}_{3} \mathrm{CN}$ and slow diffusion of diethyl ether into this solution at $-4^{\circ} \mathrm{C}$ led to the crystallization of the $\mathrm{H}-\mathrm{T}$ isomer and the yield is 50 mg ( $44 \%$ based on rhodium). The crystals were collected by filtration and the filtrate was condensed to 2 mL . The recrystallization of the $\mathrm{H}-\mathrm{H}$ isomer was achieved by slow diffusion of diethyl ether into the $\mathrm{CH}_{3} \mathrm{CN}$ solution at room temperature. $\mathrm{H}-\mathrm{T}$ isomer (19): ${ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CD}_{3} \mathrm{CN}-d_{3}\right) \delta \mathrm{ppm}$ : 7.44 (t, 2H, chp), 6.71 (d, 2H, chp), 6.33 (d, $2 \mathrm{H}, \mathrm{chp}$ ), 2.57 (s, 6 H , eq $\mathrm{CH}_{3} \mathrm{CN}$, trans to $\mathrm{N}), 2.38$ (s, 6 H , eq $\mathrm{CH}_{3} \mathrm{CN}$, trans to O ), 1.96 (s, ax $\mathrm{CH}_{3} \mathrm{CN}$ ). H-H isomer (20): ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}-d_{3}\right) \delta$ ppm: 7.38 (t, chp), 6.74 (d, chp), 6.57 (d, chp), 2.55 (s, eq $\mathrm{CH}_{3} \mathrm{CN}$, trans to N ), 2.48 (s, eq $\mathrm{CH}_{3} \mathrm{CN}$, trans to O$), 1.96\left(\mathrm{~s}\right.$, ax $\left.\mathrm{CH}_{3} \mathrm{CN}\right)$.

Preparation of cis-[ $\left.\mathbf{R h}_{\mathbf{2}}(\mathbf{f h p})_{\mathbf{2}}\left(\mathbf{C H}_{\mathbf{3}} \mathbf{C N}\right)_{6}\right]\left[\mathbf{B F}_{\mathbf{4}}\right]_{\mathbf{2}}(\mathbf{2 1})$. An amount of $\mathrm{Rh}_{2}(\mathrm{fhp})_{4}(184 \mathrm{mg}$, $0.28 \mathrm{mmol})$ was suspended in 30 mL of $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{CH}_{2} \mathrm{Cl}_{2}(\mathrm{v}: \mathrm{v}=1: 1)$. An aliquot of 1.2 mL of $\mathrm{Et}_{3} \mathrm{OBF}_{4}\left(1 \mathrm{M} \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ was added and the mixture was stirred for 4 days at room temperature. The initially green turbid mixture changed to violet and finally to red. The reaction solution was filtered to remove any insoluble materials and the filtrate was concentrated to 5 mL and treated with 50 mL of diethyl ether which led to precipitation of the desired product which was washed with copious amounts of diethyl ether to obtain a red powder. Yield: $194 \mathrm{mg}, 81 \% .{ }^{1} \mathrm{H}-\mathrm{NMR}\left(\mathrm{CD}_{3} \mathrm{CN}-d_{3}\right) \delta \mathrm{ppm}: 7.49(\mathrm{dd}, \mathrm{fhp}), 6.29(\mathrm{~d}$,
fhp), $6.21(\mathrm{~d}, \mathrm{fhp}), 2.49\left(\mathrm{eq} \mathrm{CH}_{3} \mathrm{CN}\right.$, trans to N ), $2.48\left(\mathrm{eq} \mathrm{CH}_{3} \mathrm{CN}\right.$, trans to O$), 1.96$ (free $\mathrm{CH}_{3} \mathrm{CN}$ ).

## Instrumentation and methods

X-ray data sets for all the complexes were collected on a Bruker CCD APEX diffractometer with graphite monochromated Mo $\mathrm{K} \alpha$ radiation $(\lambda=0.71073 \AA$ A $)$. Hemispheres of data for $\mathbf{1 5}$ and 18-20 were collected by a combination of four sets of Xray exposures. Each set used a different $\phi$ angle for the crystals and covered $0.3^{\circ}$ in $\omega$ for all the complexes. The exposure times were 10 s for $\mathbf{1 5}, 20 \mathrm{~s}$ for $\mathbf{1 8}, \mathbf{1 9}$ and 30 s for $\mathbf{2 0}$. The crystal parameters and information pertaining to the data collection and refinement of the crystals for $\mathbf{1 5}, \mathbf{1 8 - 2 0}$ are summarized in Table 4.1.

## Results and discussion

## Synthesis and solution characterization

Molten reactions were performed for the syntheses of $\mathbf{1 5}$ and $\mathbf{1 6}$ with an excess of Hmhp and Hchp ligands. After completion of the reactions, the excess ligands were removed by dissolution in $\mathrm{CH}_{3} \mathrm{OH}$ which led to the formation of pure (trans, syn-2, 2) isomers as evidenced by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra (Figures 4.1, 4.2 respectively), and X-ray crystallographic studies which are detailed in the following section. The crystal structures of both complexes were published in previous reports, ${ }^{226}$ but the structure obtained herein for compound 15 exhibits different unit cell parameters from the published one. Therefore, the detailed crystal data parameters are also provided in Table 4.1. Compound $\mathbf{1 7}$ was synthesized by a different method from the published one and in improved yields. ${ }^{227}$ Unlike the complex reported previously, it is only slightly soluble in

Figure $4.1{ }^{1} \mathrm{H}$-NMR spectrum of compound 15 in $\mathrm{CDCl}_{3}$.

Figure $4.2{ }^{1} \mathrm{H}$-NMR spectrum of compound 16 in $\mathrm{CDCl}_{3}$.

THF, acetone and ethanol. With the presence of several drops of DMSO, several pink solutions containing 17 with THF, acetone and ethanol were obtained.

The alkylating agent $\mathrm{Et}_{3} \mathrm{OBF}_{4}$ was used to synthesize the partial paddlewheel complex cis- $\left[\mathrm{Rh}_{2}(\mathrm{xhp})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ (18-21), similar to the method adopted by Turro et al. to prepare $\mathrm{H}-\mathrm{H}$ and $\mathrm{H}-\mathrm{T}$ cis- $\left[\mathrm{Rh}_{2}\left(\mathrm{HNOCCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}{ }^{223}$ The reaction between $\mathrm{Et}_{3} \mathrm{OBF}_{4}$ and $\mathrm{Rh}_{2}(\mathrm{mhp})_{4}$ produces only one isomer as indicated by its ${ }^{1} \mathrm{H}-\mathrm{NMR}$ (Figure 4.3) spectrum which was identified as the H-T isomer by an X-ray crystallographic study. The synthetic route adopted for cis- $\left[\mathrm{Rh}_{2}(\mathrm{chp})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$, however, resulted in the formation of both the $\mathrm{H}-\mathrm{H}$ and $\mathrm{H}-\mathrm{T}$ isomers as indicated by ${ }^{1} \mathrm{H}-$ NMR spectroscopy (Figure 4.4). This finding indicates that the alkylating agent $\mathrm{Et}_{3} \mathrm{OBF}_{4}$ does not react discriminately with the two chp ligands in the cis-positions leading to the
formation of 19, but also with the two bridging ligands occupying trans-positions which then undergo rearrangement into the more stable cis isomer to produce compound $\mathbf{2 0}$. Compound 21 was synthesized by a similar procedure to the one used for complexes $\mathbf{1 8}$ and 19 but with much longer reaction times due to the low solubility of $\mathbf{1 7}$ in the solvent. Many trials to obtain a single crystal of compound 21 were unsuccessful. From the structure of precursor 17, however, we can conclude that compound 21 adopts the $\mathrm{H}-\mathrm{H}$ configuration.

Figure $4.3{ }^{1} \mathrm{H}$-NMR spectra for compounds 18 and 21.

Figure $4.4{ }^{1} \mathrm{H}$-NMR spectra of a mixture of $\mathbf{1 9} *$ and $\mathbf{2 0} \ddagger$ (top) and pure $\mathbf{1 9} *$ (bottom) in the aromatic region in $\mathrm{CD}_{3} \mathrm{CN}$.

## X-ray crystallographic studies

cis $-\left[\mathbf{R h}_{\mathbf{2}}(\mathbf{m h p})_{\mathbf{2}}\left(\mathbf{C H}_{\mathbf{3}} \mathbf{C N}\right)_{\mathbf{6}}\right]\left[\mathrm{BF}_{4}\right]_{\mathbf{2}}$ (18). The compound crystallizes in the chiral space group $P 2_{1} 2_{1} 2_{1}$ and the cation contains two cis bridging mhp ligands in a $\mathrm{H}-\mathrm{T}$ fashion. Six $\mathrm{CH}_{3} \mathrm{CN}$ ligands complete the pseudo-octahedral coordination sphere of the central rhodium atoms (Figure 4.5) and there are two $\left[\mathrm{BF}_{4}\right]^{-}$present as counterions. One of the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands and a $\left[\mathrm{BF}_{4}\right]^{-}$counterion are disordered between two different positions with site occupancies of $0.6366 / 0.3634$ and $0.3765 / 0.6235$ respectively. Racemic twinning was refined during the last cycle, with the flack parameter 0 and the esd value 0.9416 . The $R h-R h$ bond distance is $2.4794(5) \AA$, which is $\sim 0.12 \AA$ longer than that found for $\mathbf{1 5}$ which we ascribe to the less sterically demanding bridging mhp ligands in 18. The $\mathrm{Rh}-\mathrm{N}\left(\mathrm{ax} \mathrm{CH}_{3} \mathrm{CN}\right)$ bond distances are 2.234(4) and 2.201(4) $\AA$, significantly longer than the $\mathrm{Rh}-\mathrm{N}\left(\mathrm{eq} \mathrm{CH}_{3} \mathrm{CN}\right.$ ) bond distances which are in the range of $1.999(4)-2.014$ (4) $\AA$. The Rh-N (mhp) and Rh-O (mhp) bond distances are comparable to the corresponding distances in $\mathbf{1 5}$ respectively. The distorted eq $\mathrm{CH}_{3} \mathrm{CN}$ and mhp ligands away from the eclipsed confirmation reflect the repulsion between them. The dihedral angles defined by N5-Rh1-Rh2-N7 and N6-Rh1-Rh2-N8 are $-36.5(1)^{\circ}$ and $36.9(2)^{\circ}$ respectively, larger than those in cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ and cis-$\left[\mathrm{Rh}_{2}(\mathrm{~F}-\text { form })_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} .{ }^{229}$ Slightly smaller distortions are obserbved for the two mhp bridging ligands, with the dihedral angles defined by O1-Rh1-Rh2-N2, N1-Rh1$\mathrm{Rh} 2-\mathrm{O} 2$ being $-30.3(1)$ and $-30.8(1)^{\circ}$.

Figure 4.5 Thermal ellipsoid plot of the cationic part of compound 18 at the $50 \%$ probability level; the anions and hydrogen atoms are omitted for the sake of clarity.

Figure 4.6 Thermal ellipsoid graph of the cationic unit in compound 19 at the $50 \%$ probability level; the anions and hydrogen atoms are omitted for the sake of clarity.

H-T cis-[ $\left.\mathrm{Rh}_{2}(\mathbf{c h p})_{2}\left(\mathbf{C H}_{3} \mathbf{C N}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} \cdot \mathrm{CH}_{3} \mathbf{C N}\left(\mathbf{1 9}^{\bullet} \mathbf{C H}_{3} \mathbf{C N}\right)$ : Compound $\mathbf{1 9}$ crystallizes in the space group of $P 2_{1} / \mathrm{c}$ with a coordination sphere similar to that of compound $\mathbf{1 8}$ as seen in Figure 4.6. One of the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands is disordered over two positions with a site occupancy of $0.5199 / 0.4801$. The Rh-Rh bond distance is $2.492(1) \AA, \sim 0.11 \AA$ longer than that of $\mathrm{Rh}_{2}(\mathrm{chp})_{4}$ due to the less constraints from the two bridging ligands in 19. The Rh-N $\left(\mathrm{ax} \mathrm{CH}_{3} \mathrm{CN}\right)$ bond distances are $2.21(1)$ and $2.25(1) \AA$, longer than the Rh$\mathrm{N}\left(\right.$ eq $\left.\mathrm{CH}_{3} \mathrm{CN}\right)$ bond distances ranging from 1.97(1) to 2.031(9) Å. Similar distortions from the eclipsed configuration of the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands occur, with larger distortions for the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands than those defined by the chp ligand.
$\mathbf{H}-\mathbf{H}$ cis- $\left[\mathrm{Rh}_{\mathbf{2}}(\mathbf{c h p})_{2}\left(\mathbf{C H}_{3} \mathbf{C N}\right)_{6}\right]\left[\mathbf{B F}_{4}\right]_{2} \bullet \mathbf{2 C H}_{3} \mathbf{C N}(20)$ : Compound 20 crystallizes in the space group $P-1$. The thermal ellipsoid plot of the cationic unit is displayed in Figure 4.7 and can be seen to consist of two cisoid bridging chp ligands in the H-H fashion, four eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands and one ax $\mathrm{CH}_{3} \mathrm{CN}$ coordinated to the Rh center that is bonded to the O atoms of the bridging chp ligands. The Rh-Rh bond distance is $2.505(1) \AA$, slightly longer than those in $\mathbf{1 8}$ and 19. The Rh-N $\left(\mathrm{ax} \mathrm{CH}_{3} \mathrm{CN}\right)$ bond distance is 2.114(2) $\AA$, ~ $0.1 \AA$ shorter than that in 18, $\mathbf{1 9}$ and H-T cis- $\left[\mathrm{Rh}_{2}\left(\mathrm{HNOCCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} .{ }^{223}$ The Rh-N (eq CH3 ${ }_{3} \mathrm{CN}$ ) bond distances fall in a small range of $1.989(3)$ to $2.002(2)$ Á, similar to those in 18 and 19. Much smaller distortions from the eclipsed configuration defined by the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands in $\mathbf{2 0}$ occur as compared to that found for $\mathbf{1 8}$ and $\mathbf{1 9}$, with the dihedral angles defined by N4-Rh1-Rh2-N6 and N3-Rh1-Rh2-N5 being 23.55(9) ${ }^{\circ}$ and $23.51(9)^{\circ}$. Distortions of the bridging chp ligands are only slightly smaller, with the angles being $19.35(9)^{\circ}$ and $21.74(8)^{\circ}$ respectively.

${ }^{1} H$-NMR investigations of compounds 18, 19 and 21
The exchange process of the monodentate eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands in $\mathbf{1 8}, \mathbf{1 9}$, and 21 with the NMR solvent molecule $\mathrm{CD}_{3} \mathrm{CN}$ or $\mathrm{D}_{2} \mathrm{O}$ in the dark was monitored by ${ }^{1} \mathrm{HNMR}$ spectroscopy and the results are detailed in the following section.

As shown in Figure 4.8, three different resonances in the aliphatic region are present in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of $\mathbf{1 8}$ obtained $\sim 2$ min after dissolution in $\mathrm{CD}_{3} \mathrm{CN}$, with chemical shifts of $2.63,2.47$ and 2.46 ppm , respectively. The peak at $\sim 2.63 \mathrm{ppm}$ is assigned to the $-\mathrm{CH}_{3}$ groups on the mhp ligands since its intensity does not change over the course of the experiment (vide infra). The other two closely spaced resonances are attributed to the two different sets of eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands which are trans to O and N atoms of the mhp ligands respectively. After 15 min , a distinct decrease in intensity for

Figure $4.8{ }^{1} \mathrm{H}$-NMR spectral changes of complex 18 in the dark in $\mathrm{CD}_{3} \mathrm{CN}$.
the resonance $\sim 2.47 \mathrm{ppm}$ is observed, attributed to fast exchange with the $\mathrm{CD}_{3} \mathrm{CN}$ molecules. This peak disappeared after 75 min in the dark, indicating the much faster exchange process with the $\mathrm{CD}_{3} \mathrm{CN}$ molecules than that in $c i s-\left[\mathrm{Rh}_{2}(\mu\right.$ $\left.\left.\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} .{ }^{8}$

The investigation of the lability of the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands in compound $\mathbf{1 9}$ was conducted in a similar fashion. In this case, two resonances at 2.57 and 2.38 ppm were observed corresponding to the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands trans to O and N atoms of the chp ligand respectively. As shown in Figure 4.9, the intensity of both peaks decrease simultaneously over the course of 65 h with the exchange rate for the latter resonance being much faster than that for the former one. Both exchange processes are much slower, however, than that of compound $\mathbf{1 8}$, presumably due to the weaker trans effect exerted by bridging chp ligands owing to the presence of electron withdrawing Cl substituents in 19.

For compound 21, the two types of eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands, namely either trans to the N or to the O atoms of the fhp ligands, exhibit only slightly different chemical shifts ( $\delta=$ 2.49 and 2.48 ppm$)$. The former resonance disappears over a period of $\sim 340 \mathrm{~h}$, indicating its complete substitution by $\mathrm{CD}_{3} \mathrm{CN}$ molecules whereas the latter one has only negligible changes in intensity during the same period of time (Figure 4.10). These features are ascribed to the much stronger electron withdrawing ability of the F substituents on the bridging fhp ligands.

Unit: hours

Figure $4.9{ }^{1} \mathrm{H}$-NMR spectral changes in complex 19 in the dark in $\mathrm{CD}_{3} \mathrm{CN}$; only the region involving the change in the spectra is shown.

Unit: hours

Figure $4.10{ }^{1} \mathrm{H}$-NMR spectral change for complex 21 in the dark in $\mathrm{CD}_{3} \mathrm{CN}$; only the region involving the changes in the spectra are shown.

The exchange of eq $\mathrm{CH}_{3} \mathrm{CN}$ with $\mathrm{H}_{2} \mathrm{O}$ molecules in $\mathbf{1 8}$ was also monitored by ${ }^{1} \mathrm{H}$ NMR spectroscopy in the dark. Upon dissolution in $\mathrm{D}_{2} \mathrm{O}$ the solution turns green in contrast to its red color in $\mathrm{CD}_{3} \mathrm{CN}$. A very fast substitution process involving the $\mathrm{D}_{2} \mathrm{O}$ molecules is apparently occurring, a fact that is further corroborated by the very complicated ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum and the intense signal at 2.06 ppm for free $\mathrm{CH}_{3} \mathrm{CN}$ (Figure 4.11). Similarly, for both compounds $\mathbf{1 9}$ and 21, there is also exchange of eq
$\mathrm{CH}_{3} \mathrm{CN}$ ligands with $\mathrm{D}_{2} \mathrm{O}$ molecules but at a significant slower rate as compared to that in compound $\mathbf{1 8}$ as indicated by Figures 4.12 and 4.13 respectively.

Figure $4.11{ }^{1} \mathrm{H}$-NMR spectrum of $\mathbf{1 8}$ after dissolution in $\mathrm{D}_{2} \mathrm{O}$ for 10 min , indicating very fast exchange of eq $\mathrm{CH}_{3} \mathrm{CN}$ with $\mathrm{D}_{2} \mathrm{O}$ molecules.

## Electronic absorption and electrochemical studies

The electronic absorption spectra of compounds 18, 19 and 21 were measured at room temperature in both $\mathrm{CH}_{3} \mathrm{CN}$ and $\mathrm{H}_{2} \mathrm{O}$ respectively and are summarized in Table 4.2.

Compounds 18, 19 and 21 exhibit similar electronic absorption spectroscopic properties in $\mathrm{CH}_{3} \mathrm{CN}$ at room temperature. The transitions at $\lambda \sim 498 \mathrm{~nm}$ in $\mathbf{1 8}, \lambda \sim 473$ nm for $\mathbf{1 9}$ and $\lambda \sim 491 \mathrm{~nm}$ for 21 have very similar low molar absorptivities (Table 4.2). They are tentatively assigned as the $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ to $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ charge-transfer bands but with minor LMCT character due to the dependence on the bridging ligands. Another weak but distinct feature of this series of compounds is the absorption in the region of $380-390 \mathrm{~nm}$, similar to the transitions at $\sim 350 \mathrm{~nm}$ for both the H-H and H-T isomers of cis$\left[\mathrm{Rh}_{2}\left(\mathrm{HNOCCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}^{223}$ and the transition at $\sim 363 \mathrm{~nm}$ in cis$\left[\mathrm{Rh}_{2}\left(\mathrm{OOCCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} .{ }^{8}$ These features are ascribed to combinations of

Table 4.2 Photophysical properties of 18, 19 and 21 in $\mathrm{CH}_{3} \mathrm{CN}$ and $\mathrm{H}_{2} \mathrm{O}$ at room temperature.

|  | $\lambda(\mathrm{nm}),\left(\varepsilon \times 10^{3}\left(\mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}\right)\right)$ in <br> $\mathrm{CH}{ }_{3} \mathrm{CN}$ | $\lambda(\mathrm{nm}),\left(\varepsilon \times 10^{3}\left(\mathrm{M}^{-1} \cdot \mathrm{~cm}^{-1}\right)\right)$ in $\mathrm{H}_{2} \mathrm{O}$ |

electronic transitions from $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ to $\mathrm{Rh}-\mathrm{CH}_{3} \mathrm{CN}(\mathrm{eq})\left(\sigma^{*}\right)$ and $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbitals. As shown in Table 4.2 and Figure 4.14a, medium intensity absorptions at $\sim 290-300 \mathrm{~nm}$ are also present in all three compounds. Due to the independence of the energies on the bridging ligands, these bands are also assigned as metal-centered (MC) transitions. Since they have slightly higher molar absorptivities, they correspond to the transitions originating from $\mathrm{Rh}_{2}(\pi), \mathrm{Rh}_{2}(\sigma)$ to $\mathrm{Rh}-\mathrm{CH}_{3} \mathrm{CN}(\mathrm{eq})\left(\sigma^{*}\right), \mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbitals. The electronic absorption spectra of compounds $\mathbf{1 9}$ and 21 in $\mathrm{H}_{2} \mathrm{O}$ are displayed in Figure 4.14b. The electronic absorption spectrum of compound 18, however, was not possible to obtain due to the fast exchange of eq $\mathrm{CH}_{3} \mathrm{CN}$ with $\mathrm{H}_{2} \mathrm{O}$ upon dissolution (vide supra). Slight bathochromic shifts of the lowest energy transitions occur for both compounds $\mathbf{1 9}$ and 21 when dissolved in $\mathrm{H}_{2} \mathrm{O}$ as compared to their $\mathrm{CH}_{3} \mathrm{CN}$ solutions (Table 4.2). This is similar to the situation for cis- $\left[\mathrm{Rh}_{2}\left(\mathrm{OOCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ in $\mathrm{H}_{2} \mathrm{O}$ as compared to $\mathrm{CH}_{3} \mathrm{CN}$ solution. ${ }^{8}$ The transitions at $\sim 380-390 \mathrm{~nm}$, however, are not shifted, in accord with the involvement of only the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands but not the ax ones.

The redox potentials of the synthesized compounds as well as the free bridging ligands were determined by cyclic voltammetry with the detailed results listed in Table 4.3.

a. Irreversible. ${ }^{\text {b. }}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}{ }^{c .}$ reversible ${ }^{\text {d. }}$ in $\mathrm{CH}_{3} \mathrm{CN}$, with the presence of drops of DMSO ${ }^{e}$ quasi-reversible

The strong electron donating ability of the mhp ligands renders the dimetal center electron-rich, thus leading to a cathodic shift of the first oxidation potential by $\sim 0.30 \mathrm{~V}$ in $\mathbf{1 5}$ as compared to that in $\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4} \cdot{ }^{21}$ On the other hand, it occurs at a more positive potential $\sim 1.23 \mathrm{~V}$ in $\mathbf{1 6}$, most likely due to the electron withdrawing Cl groups on the bridging chp groups. Both $\mathbf{1 5}$ and $\mathbf{1 6}$ exhibit one reversible reduction at -1.36 and -1.20 V respectively, attributed to the $\mathrm{Rh}_{2}{ }^{4+} / \mathrm{Rh}_{2}{ }^{3+}$ redox couple. The more difficult reduction for $\mathbf{1 5}$ is also in accord with the electron donating $-\mathrm{CH}_{3}$ groups resulting in an electron-rich dimetal core. Complex 17 exhibits different electrochemical properties as compared to 15 and 16, presumably because of the different ligand configuration. It exhibits one irreversible reduction at -1.49 V , one irreversible oxidation at $\sim 0.99 \mathrm{~V}$ and another quasi-reversible oxidation at $\sim 1.20 \mathrm{~V}$. For the partial paddlewheel $\mathrm{Rh}_{2}$ (II,II) compounds 18, 19 and 21, there are two irreversible reductions for compound 18 and three irreversible reductions for compounds 19 and 21. The two reductions for 18, the first two reductions for $\mathbf{1 9}$ as well as the first and third reductions for $\mathbf{2 1}$ are ascribed to stepwise reductions of the dimetal center, namely the $\mathrm{Rh}_{2}{ }^{4+} / \mathrm{Rh}_{2}{ }^{3+}$ and $\mathrm{Rh}_{2}{ }^{3+} / \mathrm{Rh}_{2}{ }^{2+}$ redox couples respectively. The third reduction in 19 and second reduction in 21 are tentatively assigned as bridging-ligand based redox events since similar features occur for the free chp and fhp ligands at -1.44 and -0.92 V respectively. One quasi-reversible oxidation appears for $\mathbf{1 8}$ and two for 21, tentatively assigned as a metal-centered oxidation but with contributions from the bridging ligands unlike the case of $\mathbf{1 9}$.

## Computational studies

To aid in the interpretation of the electronic structures of $\mathbf{1 8}, 19$ and $\mathbf{2 1}$, computational studies of their cationic units were conducted. For 18 and 19, the gas phase optimizations began with the cationic units from the crystal structures respectively while for 21, it was built in 'agui' by the modification of the crystal structure for $\mathbf{2 0}$ but with both ax positions occupied by $\mathrm{CH}_{3} \mathrm{CN}$ ligands. The calculated structures are very similar to the experimental ones for both 18 and 19 , indicating the accuracy of the levels of theory chosen and the basis sets. Important bond parameters are summarized in Table 4.4 and graphic representations of the calculated structures are displayed in Figure 4.15. TD-DFT calculations using both $\mathrm{CH}_{3} \mathrm{CN}$ and $\mathrm{H}_{2} \mathrm{O}$ as solvents were conducted based on the gas phase optimized structures. One issue that needs to be pointed out is that, due to the lability of the ax $\mathrm{CH}_{3} \mathrm{CN}$ upon solvation in $\mathrm{H}_{2} \mathrm{O}$, the TD-DFT calculations in $\mathrm{H}_{2} \mathrm{O}$ were started from the optimized cis- $\left[\mathrm{Rh}_{2}(\mathrm{chp})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{4}\left(\mathrm{H}_{2} \mathrm{O}_{a x}\right)_{2}\right]^{2+}$ and cis$\left[\mathrm{Rh}_{2}(\mathrm{fhp})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{4}\left(\mathrm{H}_{2} \mathrm{O}_{a x}\right)_{2}\right]^{2+}$ for $\mathbf{1 9}$ and $\mathbf{2 1}$ respectively.

As can be seen in Tables 4.5 and 4.6, the MO compositions of all three compounds are very similar in the two different solvents (Table 4.5 for results in $\mathrm{CH}_{3} \mathrm{CN}$ and Table 4.6 for results in $\mathrm{H}_{2} \mathrm{O}$ ). Thus, only the results from using $\mathrm{CH}_{3} \mathrm{CN}$ as solvent are presented in the following section. Orbitals HOMO and HOMO-1 are mainly the bridging ligands (mhp in 18, chp in 19 and fhp in 21) characters ( $\sim 75 \%$ in HOMO, $\sim 85 \%$ in HOMO-1); conversely, orbitals ranging from HOMO-8 to HOMO-2 are mainly Rh based orbitals. For the unoccupied orbitals, the LUMO is mainly rhodium based and the visualization indicates $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ character. The LUMO+1 and LUMO+2 have significant

anti-bonding interactions between the Rh and eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands (Figure 4.16), similar to those found in cis- $\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$. ${ }^{8}$

As displayed in Figure 4.17, the orbitals in 19 lie slightly lower than the corresponding ones in $\mathbf{1 8}$, probably due to the stabilization by the electron-withdrawing Cl groups on the bridging ligands (Table 4.5). However, different levels of stabilization occur for each orbital set, a result of different degrees of contributions from the bridging ligands to those orbitals. For example, the HOMO in 19 is $\sim 0.25 \mathrm{eV}$ lower than that in 18 while the LUMO is only by $\sim 0.08 \mathrm{eV}$ lower. This, therefore, leads to a larger HOMO-LUMO gap in 19 as compared to 18. For compound 21, its MO compositions, as listed in Table 4.5, are very similar to those in $\mathbf{1 8}$ and $\mathbf{1 9}$; however, no trend was observed for the energy of each orbital as compared to the corresponding ones in $\mathbf{1 8}$ and 19 presumably due to the $\mathrm{H}-\mathrm{H}$ orientation of two bridging ligands in 21. Nevertheless, its HOMO-LUMO gap was predicted to be $\sim 0.05 \mathrm{eV}$ smaller than that of $\mathbf{1 9}$, while $\sim$ 0.12 eV larger than that of $\mathbf{1 8}$.

On the basis of TD-DFT calculations using $\mathrm{CH}_{3} \mathrm{CN}$ as the solvent, the lowest energy bands mainly correspond to the HOMO, HOMO-3 to LUMO charge-transfer transition as shown in Tables 4.7-4.9, rendering it dual MC and MLCT characters. It is predicted at $\lambda=485,462$ and 473 nm respectively for $\mathbf{1 8}, 19$ and $\mathbf{2 1}$, in accord with the experimental data (vide supra). The bands in the region of $390-400 \mathrm{~nm}$ in all three compounds are predicted to be the transitions to the LUMO $+1 \sigma^{*}\left[\mathrm{Rh}-\mathrm{CH}_{3} \mathrm{CN}(\mathrm{eq})\right]$. Therefore, the population of the LUMO+1 orbital leads to labilization of eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands. The
absorption bands in the 330-360 nm region correspond to the transitions from HOMO-6, HOMO-3 to LUMO, LUMO+1, thus mainly of MC character.

## Concluding remarks

A series of partial paddlewheel dirhodium complexes of general formula cis$\left[\mathrm{Rh}_{2}(\mathrm{xhp})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}(\mathrm{xhp}=\mathrm{mhp}$, chp and fhp $)$ were synthesized and fully characterized by X-ray diffraction and ${ }^{1} \mathrm{H}$ NMR spectroscopy. The eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands in this family of compounds were determined to be kinetically labile upon dissolution in $\mathrm{CH}_{3} \mathrm{CN}$ or $\mathrm{H}_{2} \mathrm{O}$ in the dark, as indicated by the ${ }^{1} \mathrm{H}$ NMR and electronic spectroscopic studies. Importantly, the lability of the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands can be tuned through judicious choice of the substituents on the bridging ligands and in this case the ligand lability decreases in the order mhp> chp> fhp, which is in agreement with the hypothesis that the stronger electron donating ligands exert stronger trans effects. Irradiation of the aqueous solutions of compounds 19 and 21 with white light significantly accelerates the exchange rate of eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands for the solvent $\mathrm{H}_{2} \mathrm{O}$ molecules. This is well understood from the TD-DFT calculation results, which indicate that population of the $\sigma^{*} \mathrm{Rh}-\mathrm{N}\left(\right.$ eq $\left.\mathrm{CH}_{3} \mathrm{CN}\right)$ bonds occurs in their excited states. Consequently, compounds $\mathbf{1 9}$ and 21 hold great potential as PDT agents for cancer, investigations that are currently in progress.

## CHAPTER V

## INVESTIGATION OF PARTIAL PADDLEHWEEL DIRHODIUM COMPLEXES BRIDGED BY ORTHOMETALATED PHOSPHINE LIGANDS

## Introduction

Our previous studies revealed the exciting results that partial paddlewheel $\mathrm{Rh}_{2}$ (II,II) complexes with electron-rich bridging formamidinate and chelating electron-accepting diimine ligands, namely $c i s-\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{~N}-\mathrm{N})_{2}\right]^{2+}$ and $c i s-\left[\mathrm{Rh}_{2}(\mathrm{~F}-\text { form })_{2}(\mathrm{~N}-\mathrm{N})_{2}\right]^{2+}(\mathrm{N}-$ $\mathrm{N}=\mathrm{dpq}, \mathrm{dppz}, \mathrm{dppn}$ ) exhibit directional Ligand-to-Ligand-Charge-Transfer (LLCT) excited states. Comprehensive experimental and computational studies indicate that the excited states of these complexes exhibit superior reducing and oxidizing abilities than the commonly used $\mathrm{Ru}($ II $)$ mononuclear complexes. ${ }^{230}$ To better understand the nature of these intriguing excited states, it is imperative to investigate the charge distributions in the excited states by time-resolved techniques (transient infrared and transient absorption spectroscopies). It is also important to design other $\mathrm{Rh}_{2}$ (II,II) complexes with similar structural features but with different bridging ligands. The orthometalated phosphine ligand $\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]^{-}$discussed in chapter II is another excellent example of an electronrich bridging ligand for dirhodium(II,II) compounds. It was shown by Cotton and coworkers that compound cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ is an excellent synthetic precursor for a series of supramolecular arrays because the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands are highly labile due to the strong trans effect exerted by the two bridging $\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]^{-}$ ligands. ${ }^{105}$ As such, we chose the compound and one of its derivatives, namely, tris(4methoxyphenyl)phosphine (PMP) as bridging ligands and synthesized two series of
partial paddlewheel complexes and fully characterized them by NMR spectroscopy and X-ray crystallography. In addition, theoretical calculations were conducted which provide useful insight into the electronic structures of those complexes.

## Experimental section

## Starting materials

The starting material $\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4} \cdot 2 \mathrm{MeOH}$ was purchased from Pressure Chemical and purified by recrystallization from $\mathrm{CH}_{3} \mathrm{OH}$. The ligands tris(4methoxyphenyl)phosphine (PMP) and triphenylphosphine $\left(\mathrm{PPh}_{3}\right)$ were obtained from Sigma Aldrich and used as received. The ligands dpq (dipyrido[3,2-f:2',3'-h]quinoxaline), dppz (dipyrido[3,2-a:2', $3^{\prime}$-c]phenazine) and dppn (benzo[i]dipyrido[3,2-a:2',3'-h]quinoxaline) were synthesized according to published procedures and their purities were confirmed by ${ }^{1} \mathrm{H}$-NMR spectroscopy. The compound cis- $\left[\mathrm{Rh}_{2}(\mathrm{PMP})_{2}(\mu\right.$ $\left.\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2}$ ] was synthesized according to a slightly modified published procedure. ${ }^{228}$ The solvents acetic acid, diethyl ether and acetonitrile are of ACS grade and were used as received whereas dry $\mathrm{CH}_{3} \mathrm{CN}$ was obtained by distillation over $3 \AA$ molecular sieves under a flow of dry $\mathrm{N}_{2}$. The $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was pre-dried over $4 \AA$ molecular sieves and distilled over $\mathrm{P}_{2} \mathrm{O}_{5}$ under a flow of dry $\mathrm{N}_{2}$.

Synthesis of cis- $\left[\mathrm{Rh}_{2}\left[\mathbf{P h}_{2} \mathbf{P}\left(\mathbf{C}_{6} \mathbf{H}_{4}\right)\right]_{2}(\mathbf{d p q})_{2}\left(\mathbf{C H}_{3} \mathbf{C N}\right)\right]\left[\mathrm{BF}_{4}\right]_{2}$ (22). A quantity of cis$\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}(51 \mathrm{mg}, 0.044 \mathrm{mmol})$ was added to 20 mL of a suspension of the dpq ligand $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{CH}_{3} \mathrm{CN}$ (a 1:1/v:v mixture) ( $23 \mathrm{mg}, 0.098 \mathrm{mmol}$ ) in the dark. The solution was stirred at room temperature for 72 h , after which time the color was observed to have changed to dark red. The solution was then concentrated to 5
mL under reduced pressure and filtered through a medium frit to remove any insoluble materials. The addition of 50 mL of diethyl ether to the filtrate led to the precipitation of the desired product as a red solid; upon drying under vacuum for 24 h , an amount of 54 mg green product was obtained. The yield is $55 \mathrm{mg}, \sim 85 \%$ based on rhodium. ${ }^{1} \mathrm{H}-\mathrm{NMR}$ $\left(\mathrm{CD}_{3} \mathrm{CN}-d_{3}\right) \delta \mathrm{ppm}: 9.38(\mathrm{~d}, \mathrm{dpq}), 9.10(\mathrm{~d}, \mathrm{dpq}), 8.90(\mathrm{~d}, \mathrm{dpq}), 8.73(\mathrm{~s}, \mathrm{dpq}), 8.12(\mathrm{~m}$, $\left.\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right), 7.84(\mathrm{dd}, \mathrm{dpq}), 7.50\left(\mathrm{~m}, \mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right), 7.30\left(\mathrm{~m}, \mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right), 7.19(\mathrm{~m}$, $\left.\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right), 7.17$ (dd, dpq), $6.73\left(\mathrm{t}, \mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right)$, $6.27\left(\mathrm{dd}, \mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right)$, 6.21 (d, $\left.\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right) ;{ }^{31} \mathrm{P}-\mathrm{NMR}\left(\mathrm{CD}_{3} \mathrm{CN}-d_{3}\right) \delta \mathrm{ppm}: 19.59 \mathrm{ppm}{ }^{1} \mathrm{~J}(\mathrm{Rh}-\mathrm{P})=330 \mathrm{~Hz},{ }^{2} \mathrm{~J}(\mathrm{Rh}-\mathrm{P})=$ 45 Hz . Anal. Calcd for $\mathrm{Rh}_{2} \mathrm{C}_{64} \mathrm{H}_{44} \mathrm{P}_{2} \mathrm{~N}_{8} \mathrm{~B}_{2} \mathrm{~F}_{8} \cdot 2 \mathrm{CH}_{2} \mathrm{Cl}_{2}$ : C, 51.74; N, 7.99; H, $3.26 \%$. Found: C, 51.42; N, 7.71; H, 3.69\%.

Synthesis of cis-[ $\left.\mathbf{R h}_{2}\left[\mathbf{P h}_{2} \mathbf{P}\left(\mathbf{C}_{6} \mathbf{H}_{4}\right)\right]_{2}(\mathbf{d p p z})_{\mathbf{2}}\left(\mathbf{C H}_{3} \mathbf{C N}\right)_{2}\right]\left[\mathrm{BF}_{4}\right]_{\mathbf{2}}$ (23). A sample of cis$\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}(50 \mathrm{mg}, 0.043 \mathrm{mmol})$ was added to 20 mL of a 1:1/v:v $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{CH}_{3} \mathrm{CN}$ mixture containing $27 \mathrm{mg}(0.097 \mathrm{mmol})$ of suspended dppz. The resulting orange solution which was stirred in the dark at room temperature for 72 hours eventually turned to red and was concentrated to 5 mL and filtered through a medium frit to remove any insoluble materials. The addition of 50 mL diethyl ether to the filtrate led to the precipitation of the desired product as a brown solid, yielding 60 mg of green product after drying under vacuum for 24 h ( $90 \%$ based on rhodium). ${ }^{1} \mathrm{H}-\mathrm{NMR}$ $\left(\mathrm{CD}_{3} \mathrm{CN}-d_{3}\right) \delta \mathrm{ppm}: 9.51 \mathrm{ppm}(\mathrm{d}, \mathrm{dppz}), 8.74(\mathrm{~s}, \mathrm{dppz}), 8.43(\mathrm{~d}, \mathrm{dppz}), 8.14(\mathrm{~m}$, $\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)$ ), 8.02 (dd, dppz), 7.86 (dd, dppz), 7.38 (m, dppz), 7.33 ( $\mathrm{m}, \mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)$ ), $7.35\left(\mathrm{~m}, \mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right), 7.22\left(\mathrm{~m}, \mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right), 6.73\left(\mathrm{t}, \mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right), 6.27\left(\mathrm{dd}, \mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right)$, $6.21\left(\mathrm{~d}, \mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right) ;{ }^{31} \mathrm{P}-\mathrm{NMR}\left(\mathrm{CD}_{3} \mathrm{CN}-d_{3}\right) \delta \mathrm{ppm}: 19.36 \mathrm{ppm}{ }^{1} \mathrm{~J}(\mathrm{Rh}-\mathrm{P})=330 \mathrm{~Hz},{ }^{2} \mathrm{~J}$

## Instrumentation and methods

Hemispheres of data for 22, $\mathbf{2 3}$ and $\mathbf{2 7}$ were collected by a combination of four sets of X-ray exposures. Each set used a different $\phi$ angle for the crystals and covered $0.5^{\circ}$ in $\omega$ for $\mathbf{2 2}$ and $0.3^{\circ}$ for $\mathbf{2 3}$ and 27. The exposure times were 45 s for $\mathbf{2 2}$ and 20 s for $\mathbf{2 3}$ and 27. The electron density corresponding to heavily disordered solvent molecules observed during the data refinement was removed using the SQUEEZE routine implemented in PLATON.

## Results and discussion

## Syntheses and characterization

The synthetic route for compound 25 follows the published procedure for cis$\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} .{ }^{105} \mathrm{~A}$ slight excess of $\mathrm{Et}_{3} \mathrm{OBF}_{4}$ was used to replace each bridging $\left[\mathrm{O}_{2} \mathrm{CCH}_{3}\right]^{-}$group with two monodentate $\mathrm{CH}_{3} \mathrm{CN}$ ligands by alkylation of the carboxylates to the corresponding ester. The purity of 25 was confirmed by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectroscopic data. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of cis$\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ in $\mathrm{CD}_{3} \mathrm{CN}$, i.e., indicated all four eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands
in compound 25 undergoes fast exchange process with the $\mathrm{CD}_{3} \mathrm{CN}$ solvent molecules, as evidenced by the presence of only free $\mathrm{CH}_{3} \mathrm{CN}$ resonances in its ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum.

Syntheses of 22-24, 26-28 (structural representation shown in Figure 5.1) followed a similar procedure as described below.

Figure 5.1 Schematic representations of the complexes 22-24 and 26-28.

A suspension of slightly more than two equivalents of diimine (dpq, dppz, dppn) ligands in $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution was mixed with the $\mathrm{CH}_{3} \mathrm{CN}$ solution of cis$\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ or 25. An immediate color change to dark red was observed. Stirring at room temperature for 72 h led to full substitution of the four labile eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands with the corresponding diimine ligands, as evidenced by the ${ }^{31} \mathrm{P}$ NMR spectra of the products. The purity of each compound was also confirmed by ${ }^{1} \mathrm{H}-$ NMR spectroscopy.

## X-ray crystallography

The crystal parameters and information pertaining to the data collection and refinement are summarized in Table 5.1.
cis $-\left[\mathbf{R h}_{2}\left[\mathbf{P h}_{2} \mathbf{P}\left(\mathbf{C}_{6} \mathbf{H}_{4}\right)\right]_{2}(\mathbf{d p q})_{2}\left(\mathbf{C H}_{3} \mathbf{C N}\right)\right]\left[\mathrm{BF}_{4}\right]_{2}$. Compound 22 crystallizes in the space group $P-1$. The two rhodium centers are bridged by two cisoid $\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]^{-}$ligands in the $\mathrm{H}-\mathrm{T}$ fashion with P and C atoms as the coordination sites, akin to the starting material cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}{ }^{105}$ Each rhodium center is further chelated by one dpq ligand but with only one of the ax positions being occupied by $\mathrm{CH}_{3} \mathrm{CN}$ solvent molecule (Figure 5.2). As is the case for the compounds cis$\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}{ }^{105}$ and cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CNCH}_{3}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}{ }^{229}$, the product is a racemic mixture of both R and S isomers and they are related to each other by an inversion center. The Rh-Rh bond distance is $2.702(2) \AA, \sim 0.04 \AA$ longer than those in cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ and $\sim 0.06 \AA$ shorter than those in cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CNCH}_{3}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} .{ }^{229}$ The Rh-P and Rh-C bond distances are ~ 2.24 and $\sim 2.02 \AA$ respectively. The Rh-N (dpq, trans to C) bond length is $\sim 0.05 \AA$

Table 5.1 Crystal data for compounds $\mathbf{2 2} \cdot\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CO}, 23 \cdot \mathrm{CH}_{3} \mathrm{CN} \cdot \mathrm{C}_{4} \mathrm{H}_{10} \mathrm{O}$ and 27.

Figure 5.2 Thermal ellipsoid plot for compound 22 at the $50 \%$ probability level; anions $\left[\mathrm{BF}_{4}\right]^{-}$, hydrogen atoms and interstitial solvent molecules omitted for the sake of clarity.
longer than the Rh-N (dpq, trans to P), with the former distance being $\sim 2.20$ Å. Quite noticeably, the $\mathrm{Rh}-\mathrm{N}\left(\mathrm{ax} \mathrm{CH}_{3} \mathrm{CN}\right)$ is $2.106(6) \AA$, which is shorter than the $\mathrm{Rh}-\mathrm{N}(\mathrm{dpq})$ bond distances. The internal twists from the eclipsed configuration occur for the two dpq ligands to reduce the steric repulsion between them, with the dihedral angle values of $28.82^{\circ}$ and $28.42^{\circ}$. This is larger than those found for cis$\left[\mathrm{Rh}_{2}(\text { Fform })_{2}(\mathrm{dpq})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2}\right]\left[\mathrm{BF}_{4}\right]_{2}\left(\sim 19^{\circ}\right)$, indicating the stronger repulsions operative in this compound. ${ }^{230}$
cis $-\left[\mathbf{R h}_{2}\left[\mathbf{P h}_{2} \mathbf{P}\left(\mathbf{C}_{6} \mathbf{H}_{4}\right)\right]_{2}(\mathbf{d p p z})_{2}\left(\mathbf{C H}_{\mathbf{3}} \mathbf{C N}\right)_{2}\right]\left[\mathbf{B F}_{4}\right]_{2}$. Compound $\mathbf{2 3}$ crystallizes in the space group $P 2_{1} / \mathrm{c}$. The coordination spheres of the rhodium centers are similar to that of $\mathbf{2 2}$, except that both ax positions are occupied by $\mathrm{CH}_{3} \mathrm{CN}$ ligands as shown in Figure 5.3. As in the case of $\mathbf{2 2}$, compound $\mathbf{2 3}$ is a racemic mixture, but the two isomers are related to each other by glides located at $1 / 4 \mathrm{~b}$ and $3 / 4 \mathrm{~b}$. The Rh-Rh bond distance is $2.7186(6) \AA$, comparable to that in 22. The Rh-P and Rh-C bond distances are $\sim 2.2503(4)$ and $\sim$ $2.0400(3) \AA$, similar to those in cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ and 22, but shorter than those found in cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CNCH}_{3}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2} .{ }^{229}$ The Rh-N (dppz, trans to C atoms) bond distances are $\sim 2.19 \AA, \sim 0.05 \AA$ longer than the Rh-N (dppz, trans to P atoms) bond distances. On average, both of them are longer than those in cis-$\left[\mathrm{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})_{2}\left(\eta^{1}-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)\right]\left[\mathrm{BF}_{4}\right]^{46}$ (from 2.005(4) to 2.016(4) $\AA$ ) and $c i s-\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{dppz})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)\right]\left[\mathrm{BF}_{4}\right]_{2}$ (from 2.040(5) to $\left.2.060(2) \AA\right)^{230}$ indicating the much stronger trans influence of the bridging orthometalated phosphine ligands. The Rh-N (ax CH3CN) bond distances are 2.2437(5) and 2.1953(5) $\AA$, respectively, in a similar range to $\mathrm{Rh}-\mathrm{N}$ (dppz, trans to C atoms). The internal twist angles from the eclipsed configuration for two dppz ligands are $-21.65^{\circ}$ and $-21.61^{\circ}$, which are larger than those in cis- $\left[\operatorname{Rh}_{2}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}(\mathrm{dppz})_{2}\left(\eta^{1}-\right.\right.$ $\left.\left.\mathrm{O}_{2} \mathrm{CCH}_{3}\right)\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)\right]\left[\mathrm{BF}_{4}\right]\left(\sim 13^{\circ}\right)$ and cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{dppz})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)\right]\left[\mathrm{BF}_{4}\right]_{2}(\sim$ $16^{\circ}$ ).

Figure 5.3 Thermal ellipsoid representation of compound $\mathbf{2 3}$ at the $50 \%$ probability level; anions and hydrogen atoms were omitted for the sake of clarity.
cis $-\left[\mathbf{R h}_{2}[\mathbf{P M P}]_{2}(\mathbf{d p p z})_{\mathbf{2}}\left(\mathbf{C H}_{3} \mathbf{C N}\right)_{2}\right]\left[\mathbf{B F}_{4}\right]_{2}$. Compound 27 crystallizes in the triclinic $P-1$ space group, with the coordination environment around the two rhodium centers similar to 23 being depicted in Figure 5.4a. Compound 27 is also a racemic mixture with the isomers related to each other by an inversion center. The Rh-Rh bond distance is 2.723(1) $\AA$, in a similar range to that found for 22 and 23 . The Rh-N (dppz) bond distances trans to the P atoms are $\sim 2.12 \AA$ while those trans to C atoms are $\sim 2.19 \AA$, and both distances are in a similar range to those in 23 . The Rh-N $\left(\mathrm{ax} \mathrm{CH}_{3} \mathrm{CN}\right)$ bond distances are $\sim 2.19 \AA$, similar to the Rh-N (dppz, trans to C) bond distances. Distortions from the eclipsed configuration for the two dppz ligands also occur in the crystal structure, and the dihedral angles defined by N1-Rh1-Rh2-N3 and N2-Rh1-Rh2-N4 are -24.5(1) ${ }^{\circ}$ and $24.4(1)^{\circ}$ respectively. As shown in Figure 5.4 b, intermolecular $\pi-\pi$ stacking interactions
are present in the crystal packing diagram of 27 , with a distance of $\sim 3.36 \AA$ from C75 to the plane that is defined by the dppz ligand from another molecule.

Figure 5.4 (a) Thermal ellipsoid representation of compound 27 at the $50 \%$ probability level; anions and hydrogen atoms were omitted for the sake of clarity; (b) crystal packing representations of 27 , indicating the $\pi-\pi$ stacking interactions between two dppz ligands in two adjacent molecules.

## Electronic absorption and electrochemical studies

Since there are structural similarities between 22/26, 23/27, 24/28, respectively, each pair is expected to exhibit analogous electronic properties in $\mathrm{CH}_{3} \mathrm{CN}$ at room temperature (Figures 5.5 and 5.6) which are detailed in this section. Although the $\varepsilon$ values are low, two distinct shoulder peaks are observed in the region $\lambda>410 \mathrm{~nm}$ for all the complexes. The first shoulder peak, at $\sim 420 \mathrm{~nm}$ for 22/26, $\sim 440 \mathrm{~nm}$ for 23/27 and $\sim 470 \mathrm{~nm}$ for $\mathbf{2 4} / \mathbf{2 8}$ (Table 5.2), is clearly dependent on the identity of the diimine ligands with the absorption bands for compounds containing more conjugated $\pi$ system ligands occurring at relative lower energies. Therefore, they can be assigned as the electronic transitions from the metal centers to the diimine ligands (MLCT). As featured in Figure 5.5 and Table 5.2, the lowest energy transitions in $\mathbf{2 2}$ and $\mathbf{2 3}$ are of nearly the same energy with similar molar absorptivities $\left(\sim 477 \mathrm{~nm}, \varepsilon=1250 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right.$ in 22 and $\sim$ $474 \mathrm{~nm}, 1250 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ in 23). For compound 24, however, the transition occurs at a lower energy with a slightly higher molar absorptivity ( $\sim 518 \mathrm{~nm}, \varepsilon=2000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ ), an indication of the different character in 24. Furthermore, as shown in Figure 5.6 and Table 5.2, the lowest energy transitions in $\mathbf{2 6}$ and $\mathbf{2 7}$ also occur in a very similar energy range as compared to that of $\mathbf{2 2}$ and $\mathbf{2 3}$. The independence of these transitions on both the bridging and chelating ligands indicates that they are MC dd transitions, not uncommon for $\mathrm{Rh}_{2}$ (II,II) compounds. ${ }^{21}$ The relatively high $\varepsilon$ value $\left(\sim 1000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$, however, indicates that they are likely of different characters from the lowest energy transition band in $\mathrm{Rh}_{2}\left(\mu-\mathrm{OOCCH}_{3}\right)_{4} \bullet 2 \mathrm{H}_{2} \mathrm{O}\left(\sim 584 \mathrm{~nm}, \sim 240 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right.$ in $\left.\mathrm{H}_{2} \mathrm{O}\right)$ which corresponds to the $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ to $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ transition. The absorptions at $\lambda \sim 302$ and 339 nm
for $\mathbf{2 2}, 361$ and 378 nm for $\mathbf{2 3}, 398$ and 418 nm for $\mathbf{2 4}$ are assigned as the diimine centered intramolecular ${ }^{1} \pi \pi^{*}$ transitions, given that similar absorption bands are also present in the free dpq ligand at $\sim 326-340 \mathrm{~nm}$, the free dppz ligand at $\sim 340-370 \mathrm{~nm}$ and the free dppn ligand at $\sim 390$ and 414 nm . In addition, similar absorptions are also observed for compounds 26-28 with similar molar absorptivities, the series of $\mathrm{Rh}_{2}$ (II,II) compounds with different bridging ligands ([DTolF $]^{-}$, $[\mathrm{F}-\mathrm{form}]^{-}$and $[\mathrm{OAc}]^{-}$), as well as

Figure 5.5 Overlay of the electronic absorption spectra of compounds $\mathbf{2 2 - 2 4}$ in $\mathrm{CH}_{3} \mathrm{CN}$ at room temperature.

Figure 5.6 Comparisons of the electronic absorption spectra between 22/26, 23/27 and 24/28.
several $\mathrm{Ru}(\mathrm{II})$ compounds containing these diimine ligands. ${ }^{36,37,44-48,230}$ Other strong absorption maxima in these compounds are located at $\lambda \sim 250 \mathrm{~nm}$ in 22 and 26, $\sim 270$
nm in 23 and 27, $\sim 260 \mathrm{~nm}$ in 24 and 28, ascribed to the electronic transitions between the metal based orbitals but perturbed by mixing with the diimine ligands.

Upon a strong reducing potential to the working electrode of $\mathrm{CH}_{3} \mathrm{CN}$ solutions containing compounds $\mathbf{2 3}, \mathbf{2 4}, 27$ and $\mathbf{2 8}$, changes in the cyclic voltammogram were observed, indicating the decomposition of those complexes; positive voltages do not casue degradation. Of all the compounds, there is one quasi-reversible oxidation, occurring at $\sim 1.30 \mathrm{~V}$ for compounds $\mathbf{2 2 - 2 4}$, and at $\sim 1.25 \mathrm{~V}$ for compounds 26-28. A similar process is also observed in cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ at $\sim 1.41 \mathrm{~V}$, assigned as the $\mathrm{Rh}_{2}{ }^{4+} / \mathrm{Rh}_{2}{ }^{5+}$ redox couple. ${ }^{105}$ In the case of compounds 22-24, 26-28, these events are independent of the diimine ligands while electron-donating groups on the bridging ligands result in a cathodic shift which idicates a $\mathrm{Rh}_{2}{ }^{4+} / \mathrm{Rh}_{2}{ }^{5+}$ oxidation process influenced by the bridging ligands.

There are four consecutive reduction processes for compounds 22 and 26. The first two reduction processes occur at $\sim-0.76$ and -1.03 V in $\mathbf{1},-0.86$ and -1.08 V in $\mathbf{2 6}$, tentatively assigned as the stepwise reductions of the two diimine ligands. Compared to 22, these processes for compound 26 occur at a more negative potential ( $\sim 0.1 \mathrm{~V}$ ), underscoring the involvement of the bridging ligands which is also in accord with the electron donating groups resulting in greater difficulty to reduce them. The third and fourth reduction events are tentatively assigned to the stepwise reduction of the dimetal centers, namely, the $\mathrm{Rh}_{2}{ }^{4+} / \mathrm{Rh}_{2}{ }^{3+}$ and $\mathrm{Rh}_{2}{ }^{3+} / \mathrm{Rh}_{2}{ }^{2+}$ redox couples.

## Computational studies

DFT and TD-DFT calculations of the cationic units in 22-24, 26-28 were conducted to gain further understanding of their electrochemical and photophysical properties. Geometric parameters for the gas phase optimizations were obtained from the crystal structures of 22, 23, 27 with appropriate modifications of the diimine ligands for different compounds (dpq for 26, dppn for 24 and 28). The optimized cationic units of 23 and 27 are shown in Figure 5.7. The comparisons of the bond distances and bond angles between the calculated structures and the crystal structures are listed in Table 5.3.

In all six compounds, orbitals ranging from LUMO to LUMO+5 are mainly diimine based orbitals, whereas the LUMO+6 is mainly of $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ character (Table 5.4). For the HOMOs in 22-24, different compounds vary in character and they are detailed as follows. For 22 and 23, they possess similar compositions, mainly $\mathrm{Rh}_{2}(\sigma)$ character with small contributions from ax $\mathrm{CH}_{3} \mathrm{CN}(\sim 10 \%)$ and bridging ligands ( $\sim 10 \%$ ), whereas it is a dppn-centered orbital in 24. The HOMO-1 in 24, on the other hand, has the same character as the HOMOs in 22 and $23\left(\mathrm{Rh}_{2}(\sigma)\right.$ orbital). Metal-centered $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ orbitals are HOMO-3, HOMO-4 in 22 and 23 (Table 5.4) and HOMO-5 [83\% (Rh), 9\% $\left.\left(\mathrm{Ph}_{2} \mathrm{PC}_{6} \mathrm{H}_{4}\right)\right]$ and HOMO-6 $\left[70 \%(\mathrm{Rh}), 22 \%\left(\mathrm{Ph}_{2} \mathrm{PC}_{6} \mathrm{H}_{4}\right)\right]$ in 24. For the HOMOs in 2628, they are mainly $\mathrm{Rh}_{2}(\sigma)$ character $\left(70 \% \mathrm{Rh}_{2}, 15 \%\right.$ PMP and $10 \%$ ax $\left.\mathrm{CH}_{3} \mathrm{CN}\right)$. The metal-centered $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ orbitals are HOMO-9 in $26[72 \%(\mathrm{Rh}), 19 \%$ (PMP)] and 27 [71\% (Rh), $22 \%$ (PMP)] and HOMO-11 in 28. One point worth mentioning is that the HOMO1 and HOMO-2 in 28, are mainly dppn-based orbitals.

Figure 5.7 Calculated cationic structures of compounds 23 and 27; the hydrogen atoms were omitted for the sake of clarity.

For all six compounds, the energies for the orbitals ranging from LUMO to LUMO+5 are closely related to the diimine ligands as displayed in Figure 5.8 due to their diimine ligand characters, which is similar to the observation in the other two series of dirhodium compounds equipped with $[\mathrm{DTolF}]^{-}$and $[\mathrm{F} \text {-form }]^{-}$ligands. ${ }^{230}$ On the other hand, the LUMO+6 orbitals lie in very close energy range for all the complexes due to their $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ character. The HOMOs in $\mathbf{2 2}$ and $\mathbf{2 3}$ and the HOMO-1 in $\mathbf{2 4}$ are of very similar energies due to their comparable $\mathrm{Rh}_{2}(\sigma)$ character (Table 5.4). The HOMO and HOMO2 in $\mathbf{2 4}$ (dppn-centered orbital) also lie in a very similar range as the HOMO-1 in $\mathbf{2 4}$ as depicted in Figure 5.8. The HOMOs in 26-28 lie very close in energy as displayed in Figure 5.8, but are of slightly higher energy than the HOMOs in 22-23 and HOMO-1 in 24 (Table 5.4), ascribed to the electron donating -OMe groups on the phenyl rings of the bridging ligand which is a minor component of the HOMOs in all six compounds. The HOMO-1 and HOMO-2 in $\mathbf{2 8}$ are of very similar energy to the HOMO and HOMO-2 in 24 due to their same dppn ligand character (Table 5.4).

The vertical energies, the orbital contributions and oscillating factors for the first 10 excited states in 22-24, 26-28 are listed in Tables 5.5 and 5.6, respectively. The lowest energy transitions in 22-23, 26-27 have similar character, mainly the electronic transitions from $\mathrm{Rh}_{2}(\sigma) / \mathrm{Rh}_{2}\left(\pi^{*}\right)$ orbitals to $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ orbital (Tables 5.5 and 5.6). Therefore, they occur within a very small energy range of 470 to 475 nm with a similar oscillating factor of $f \sim 0.02$; the lowest energy transitions for 24 and 28, however, occur at $\sim 500-510 \mathrm{~nm}$ and they are of dual ${ }^{1} \pi \pi^{*}$ dppn-centered and metal to dppn ligand charge transition character (MLCT) as revealed by the TD-DFT calculations.

On the other hand, the transitions originating from $\mathrm{Rh}_{2}(\sigma) / \mathrm{Rh}_{2}\left(\pi^{*}\right)$ to $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ in $\mathbf{2 4}$ and 28, occur at $\lambda \sim 473 \mathrm{~nm}$, which is similar to the lowest energy transitions for 22, $\mathbf{2 3}$ and 26, 27. Other distinct low energy transition are predicted to occur at $\lambda \sim 420-430 \mathrm{~nm}$ in 22, $430-440 \mathrm{~nm}$ in $\mathbf{2 3}, 480-490 \mathrm{~nm}$ in $\mathbf{2 4}$. They are the transitions from metal-based orbitals to the low lying diimine based unoccupied orbitals, thus rendering them MLCT character. The bathochromic shifts on going from 22 through 24 are in accord with the order of the energy levels for those diimine based unoccupied orbitals being dpq>dppz> dppn. Similar bands also occur in compounds 26-28, with all of them also bathochromicshifted as compared to 22-24 respectively, attributed to the slight destabilization of the $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ orbitals by the more electron donating bridging PMP ligands in them (vide supra).

## Concluding remarks

The complexes presented in this chapter comprise two new families of partial paddlewheel dirhodium compounds with orthometalated phosphines as bridging ligands that exhibit novel structural features, in particular the very long eq $\mathrm{Rh}-\mathrm{N}$ bond distance. This finding is not surprising given the fact that the orthometalated phosphine ligands are very good electron donors (vide supra), that exert a strong trans influence on these eq Rh-N bonds. Preliminary studies indicate that the lowest energy transitions in the dpq, dppz complexes are mainly of metal-centered character whereas the dppn analogs are dual dppn $\pi \pi^{*}$ and $\mathrm{Rh}_{2}\left(\pi^{*}\right)$ to $\mathrm{Rh}_{2}\left(\sigma^{*}\right)$ character. As compared to the results obtained from the studies in Chapter III, the use of orthometalated phosphine ligands leads to a
drastic change of the electronic structures of the dirhodium complexes, indicating an ease of tuning of the ligand field.

## CHAPTER VI

## CONCLUDING REMARKS AND FUTURE WORK

As described in the previous chapters, the new dirhodium complexes exhibit potential for two very different applications, namely solar energy conversion (specifically water splitting to produce hydrogen) and anticancer photodynamic applications. These properties are directly related to the nature of the bridging ligands spanning the dirhodium metal-metal bond. To further improve their performance in each arena the ligand environment was tuned.

The ultimate goal for the partial paddlewheel dirhodium complexes in Chapters II and IV was to achieve stability of the complexes with respect to lack of substitution of the monodentate eq ligands and to induce photolability upon visible light irradiation; in this respect, the aim was a medicinal chemistry application. As demonstrated in this dissertation, the incorporation of electron rich bridging ligands, e.g. formamidinate or orthometalated phosphine ligands, leads to an electron rich dimetal core which renders the monodentate eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands labile even in the absence of light. The use of the better electron accepting $\mathrm{CH}_{3} \mathrm{NC}$ ligand results in the formation of partial paddlewheel dirhodium isocyanide complexes, in which the eq $\mathrm{CH}_{3} \mathrm{NC}$ ligands bind so strongly to the dimetal center that they are stable even with light irradiation. By using the less electrondonating pyridinate ligand with different substituents as described in Chapter IV, one can systematically tune the electronic structures of the dirhodium complexes which further sheds light on the structure/reactivity relationships for this class of partial paddlewheel dirhodium complexes.

Given the above issues, a promising idea is to coordinate $\mathrm{CH}_{3} \mathrm{NC}$ ligands to cis$\left[\mathrm{Rh}_{2}(\mathrm{mhp})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ for which it is known that the eq $\mathrm{CH}_{3} \mathrm{CN}$ ligands are less labile than those in cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ but more labile than those in the case of cis- $\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$. Therefore, the resulting compound, namely cis- $\left[\mathrm{Rh}_{2}(\mathrm{mhp})_{2}\left(\mathrm{CNCH}_{3}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$, is expected to possess stable eq $\mathrm{CH}_{3} \mathrm{NC}$ ligands in the dark but may achieve the desired photolability upon visible light irradiation.

Partial paddlewheel dirhodium complexes with formamidinate bridging ligands presented in Chapter III and those with orthometalated phosphine bridging ligands in Chapter IV exhibit very different photophysical properties, further underscoring the important role of the bridging ligands. Of particular interest, preliminary studies on compound 9 from Chapter III, namely cis-[ $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{dpq})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)\right]\left[\mathrm{BF}_{4}\right]_{2}$ indicate its ability to catalytically reduce $\mathrm{H}^{+}$to $\mathrm{H}_{2}$ upon visible light irradiation in the absence of any external photosensitizer. This result opens up a new strategy for incorporating the water reduction catalyst and photosensitizer into a single molecule without the complicated synthesis and purification processes. Moreover, compounds based on this strategy can also eliminate the undesired electron transfer process from the photosensitizer to the water reduction catalyst, thereby increasing the efficiency of the $\mathrm{H}_{2}$ production process. We propose that the $\mathrm{H}_{2}$ production ability of compound 9 is closely related to the highly reducing ${ }^{3} \mathrm{MC}$ excited state, which can facilitate the formation of Rh hydride species. Therefore, the development of other dirhodium complexes with a similar structural type should also utilize electron rich donating ligands to render the excited states of the dirhodium complexes highly reducing. For
example, oxopyridinate or acetamide ligands should be utilized to further tune the properties of this type of partial paddlewheel dirhodium complexes. In this vein, compounds cis- $\left[\mathrm{Rh}_{2}(\mathrm{xhp})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ and cis- $\left[\mathrm{Rh}_{2}\left(\mathrm{NHCOCH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ are readily available as the synthetic precursors for compounds cis- $\left[\mathrm{Rh}_{2}(\mathrm{xhp})_{2}(\mathrm{~N}-\right.$ $\left.\mathrm{N})_{2}\right]\left[\mathrm{BF}_{4}\right]_{2}$ and cis- $\left[\mathrm{Rh}_{2}\left(\mathrm{NHCOCH}_{3}\right)_{2}(\mathrm{~N}-\mathrm{N})_{2}\right]\left[\mathrm{BF}_{4}\right]_{2}(\mathrm{~N}-\mathrm{N}=\mathrm{dpq}$, dppz or dppn ligands $)$.

## Improving water solubility

For the better performance as catalysts or as anticancer agents, one goal of primary importance is to develop complexes with higher water compatibility as compared to the current ones. For example, the complexes cis- $\left[\mathrm{Rh}_{2}(\mathrm{DTolF})_{2}(\mathrm{~N}-\mathrm{N})_{2}\right]^{2+}$ and $c i s-\left[\mathrm{Rh}_{2}(\mathrm{~F}-\right.$ form $\left.)_{2}(\mathrm{~N}-\mathrm{N})_{2}\right]^{2+}$ in chapter III as well as cis- $\left[\mathrm{Rh}_{2}\left[\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]_{2}(\mathrm{~N}-\mathrm{N})_{2}\right]^{2+}$ in chapter V $(\mathrm{N}-\mathrm{N}=\mathrm{dpq}, \mathrm{dppz}, \mathrm{dppn})$ have very limited water solubility.

The introduction of hydrophilic groups (carboxylic acids ${ }^{231}$, sulfonic acids ${ }^{232-234}$ or ammonium groups ${ }^{235}$ ) onto the scaffold of organic ligands is an effective way of imparting higher water solubility to coordination complexes. Diarylformamidine ligands offer many possibilities for the improvement of water solubility through variation of the substituents at different positions on the phenyl groups. The proposed synthetic route for formamidine ligands with sulfonate/carboxylate groups is outlined in Figure 6.1.

Another commonly applied strategy to enhance water solubility of organic ligands is to incorporate hydrophilic peptides as functional groups. One common linker group between the organic ligands and the peptides is carboxylate, ${ }^{236}$ which can be readily attached to the formamidine ligands according to the synthetic route depicted in Figure 6.1. The structures of the proposed peptides ${ }^{237-238}$ are displayed in Figure 6.2 and the

Figure 6.1 Synthetic route for formamidine ligands bearing sulfonate or carboxylate groups.

Figure 6.2 Structural representations of the proposed peptides to enhance the water solubility of the formamidine ligands.

Figure 6.3 Synthetic routes for the coupling reaction between peptides and formamidine ligands.
detailed procedure for the coupling reactions between the carboxylate group and the peptides is described in Figure 6.3. ${ }^{239}$

Betaine (Figure 6.4) is a chemically neutral zwitterion with a positively charged cationic group and a negatively charged functional group. It is widely used in biology and biochemistry to increase the water solubility of various types of drugs and proteins. ${ }^{240-241}$ The proposed synthetic route for formamidine ligands bearing a sulfobetaine group is detailed in Figure 6.4. The sulfobetaine can be easily obtained by the reaction of a tertiary amine with 1,3-propanesultone in toluene. ${ }^{242}$ The resulting product is then reacted with the p-iodoaniline in DMF catalyzed by $\left[\operatorname{Pd}(0)\left(\mathrm{PPh}_{3}\right)_{4}\right]$ through a Sonogashira cross-coupling reaction to form the para-substituted aniline. ${ }^{243}$ Subsequent reaction with triethylorthoformate generates the desired formamidine ligands.

Figure 6.4 Schematic representation of trimethylglycine (betaine).

## Design of dual functionality PDT agents for cancer therapy

One burgeoning area in the development of effective PDT anticancer drugs is the design and synthesis of dual-action phototherapeutic agents. For example, Turro and coworkers designed several $\mathrm{Ru}(\mathrm{II})$ complexes with 5-CNU (5-CNU $=5$-cyanouracil, an anticancer active drug) as the monodentate ligands (the structural representation of cationic unit of
compound $\left[\mathrm{Ru}(\right.$ tpy $\left.)(5-\mathrm{CNU})_{3}\right] \mathrm{Cl}_{2}$ is shown in Figure 6.5). Upon light irradiation, the 5CNU molecule can be released from the parent compounds. Therefore, the in situ generated compounds, $5-\mathrm{CNU}$ and $\mathrm{Ru}(\mathrm{II})$ complex have synergic effect and can achieve higher cytotoxicity towards cancer cell. ${ }^{222,244}$

Figure 6.5 Structural representation of $\left[\mathrm{Ru}(\mathrm{tpy})(5-\mathrm{CNU})_{3}\right]^{2+}$.

The same strategy can also be applied to synthesize photoactive $\mathrm{Rh}_{2}$ (II,II) compounds. For example, it has been shown in chapter $V$ that the complex $\mathrm{H}-\mathrm{H}$ cis$\left[\mathrm{Rh}_{2}(\mathrm{fhp})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ has two relatively labile eq $\mathrm{CH}_{3} \mathrm{CN}$ in the dark which undergo ligand exchange with the $\mathrm{CD}_{3} \mathrm{CN}$ molecules. Therefore, it is reasonable to react the complex with 1 eq of diimine ligand, e.g. dpq, to replace these two labile $\mathrm{CH}_{3} \mathrm{CN}$ ligands. The resulting product, cis- $\left[\mathrm{Rh}_{2}(\mathrm{fhp})_{2}(\mathrm{dpq})\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}\right]\left[\mathrm{BF}_{4}\right]_{2}$ should be able to subsequently undergo substitution reactions with the $5-\mathrm{CNU}$ ligands to generate cis-$\left[\mathrm{Rh}_{2}(\mathrm{fhp})_{2}(\mathrm{dpq})(5-\mathrm{CNU})_{3}\right]\left[\mathrm{BF}_{4}\right]_{2}$. The detailed synthetic route is described in Figure 6.6 Presently, compound cis-[ $\left.\mathrm{Rh}_{2}(\mathrm{fhp})_{2}(\mathrm{dpq})\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}\right]\left[\mathrm{BF}_{4}\right]_{2}$ has been successfully synthesized, the identity of which was confirmed by an X-ray crystallographic study
(Figure 6.7); the purity was verified by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy (Figure 6.8). The four resonances at $\sim 9.70,9.29,9.00$ and 8.19 ppm correspond to the dpq ligand, while the

$\mathrm{L}=\mathrm{CH}_{3} \mathrm{CN}$

Figure 6.6 Detailed synthetic route to generate cis- $\left[\mathrm{Rh}_{2}(\mathrm{fhp})_{2}(5-\mathrm{CNU})_{3}\right]\left[\mathrm{BF}_{4}\right]_{2}$.

Figure 6.7 Thermal ellipsoid plot for compound cis- $\left[\mathrm{Rh}_{2}(\mathrm{fhp})_{2}(\mathrm{dpq})\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}\right]\left[\mathrm{BF}_{4}\right]_{2}$ at the $50 \%$ probability level. Anions and hydrogen atoms were omitted for the sake of clarity.

Figure 6.8 ${ }^{1} \mathrm{H}$-NMR spectrum for cis- $\left[\mathrm{Rh}_{2}(\mathrm{fhp})_{2}(\mathrm{dpq})\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}\right]\left[\mathrm{BF}_{4}\right]_{2}$ in the aromatic region measured in $\mathrm{CD}_{3} \mathrm{CN}$ at room temperature.
three resonances at $\sim 7.64,6.66$, and 6.27 ppm result from the three different types of protons on the bridging fhp ligands.

In conclusion, the dirhodium complexes described in this thesis constitute new families of compounds that exhibit interesting and intriguing structural and electronic properties. Further studies involving the new compounds described in the chapter and their respective applications, such as photocatalyzing water reduction to generate $\mathrm{H}_{2}$ and PDT agents for cancer, are currently in progress.
