ABSTRACT

Cotton (*Gossypium. Spp.*) is an agroeconomically significant crop worldwide involved in textile, oil, and feedstock production. Identifying genetic targets involved with disease resistance in cotton remains a critical objective for the scientific community. There remains much to be elucidated about how plant cells communicate and recognize biotic and abiotic environmental cues. Cell-surface-associated pattern recognition receptors (PRR) play a critical role in pathogen recognition. In plants, PRRs are receptor-like kinases (RLKs) and receptor-like proteins (RLPs). In particular, leucine-rich repeat containing RLPs (LRR-RLPs) have been indicated to play an important role in disease resistance against *Fusarium* infection in Arabidopsis. My thesis research is to genome-wide identify cotton RLPs with a bioinformatics approach and characterize their potential involvement in cotton disease resistance using virus-induced gene silencing (VIGS) approach. The 57 Arabidopsis RLPs were used to identify the cotton RLPs via sequence homology. Analysis of the cotton genome has identified 86 LRR-RLPs in *G. arboreum*, 107 LRR-RLPs in *G. raimondii*, and 151 LRR-RLPs in *G. hirsutum*. Phylogenetic tree analysis with other plant LRR-RLPs suggested that cotton LRR-RLPs are likely evolved independently and clustered together. LRR-RLPs appear to be evolved rapidly as the homology between cotton and Arabidopsis LRR-RLPs is often below 40%. The number of LRRs varies among different LRR-RLP members. Using the VIGS approach, we silenced a set of cotton RLPs. My preliminary assays suggested that GhRLPGSO1-like, GhRLP44, GhRLP6, and GhRLP34 might be required

for defense against *Fusarium oxysporum*. Additional infection assays and evaluation of silencing efficiency will further evaluate their involvement in disease resistance.

ACKNOWLEDGEMENTS

I would like to thank my committee chair, Dr. Libo Shan, and my committee members, Dr. Ping He, and Dr. David M. Stelly for their guidance and support throughout this research. I would like to thank the Ministry of Food, Agricultural, and Livestock and Department of the General Directorate Agricultural Research and Policy in Turkey. I would like to thank also go to my friends and the department faculty and staff for making my time at Texas A&M University a great experience. I would like to thank to Kevin Babilinia, Ping Wang, Dr. Maoying Li, Dr. Fangjun Li, Kevin Cox, Pierce Jamieson, and colleagues. Finally, I would like to thank to my family for their encouragement.

CONTRIBUTORS AND FUNDING SOURCES

This work was supervised by a thesis committee consisting of Professor Dr. Libo Shan and Dr. David M. Stelly of the Department of Molecular and Environmental Plant Science and Professor Dr. Ping He of the Department of Biochemistry and Biophysics.

All other work conducted for the thesis was completed by the student independently. Mr. Cilkiz is sponsored by the Ministry of National Education of Turkey.

1. INTRODUCTION

Cotton (*Gossypium. Spp.*) is an agroeconomically significant crop worldwide involved in textile, oil, and feedstock production. (Chen J.Y., et al. 2015). The *Gossypium* genus contains 46 diploid species that can be categorized into eight groups comprising A-G, and K, and six allotetraploid species (Li, F., et al. 2015). There are commercially only four species, which are the allotetraploid of the *G. hirsutum*, and *G. barbadense* and the diploid of the *G. arboreum*, and *G. herbaceum* (Zhang H.B., et al 2008).

The diploid genomes (A- and D-) stems from the identical eudicot ancestor about 5-10 million years ago (MYA). It is believed that after the hybridization of the A- and D-genome cotton transpired five allotetraploid species polyploidized approximately 1-2 MYA (Li, F. et al. 2015). Evolutionary analysis has illustrated that *G. hirsutum* ($4n = 4x = 52$; AADD genome) is a hybrid of two diploid species, *G. arboreum* ($2n = 2x = 26$; AA genome) and *G. raimondii* (DD genome). The whole genome sequences of *G. hirsutum*, *G. arboreum*, and *G. raimondii* have been released for further studies (Zhang, H.B., et al. 2008; Li, F., et al. 2015; Paterson, A. H., et al. 2012).

Many pathogenic organisms including viruses, bacteria, fungi, and nematodes attack plants. Previous studies have shown that induced defense responses provide resistance capacity to these pathogenic attacks with plant disease resistance (R) proteins, in a gene-for-gene interaction. Our understanding of the molecular mechanism of gene-for-gene disease resistance has been improved due to identifying R genes and the corresponding Avirulence (Avr) genes (Kruijt, M., et al, 2005). In this case, induced

defense responses result from the recognition of Avr proteins by R genes. The *Avr* genes and induce defense responses are required to recognize products by producing plant disease resistance. (Xiao S, et. al. 2003).

Previous studies have been predominantly investigating non-peptide phytohormones, such as auxin, cytokinin, and gibberellin, and their back-and-forth interactions to clarify the principal signal transduction pathways and the different function of these hormones on plant growth, development, and reproduction in plants since 1950s. On the other hand, the recent studies have shown that many signaling events in plants are activated by small diverse secreted peptides as known elicitors. The common consensus is that the elicitors interact with extracellular membrane receptors to trigger activation of defense response and growth related genes (Uebler S., and Dresselhaus T., 2014).

One of the more crucial questions in plant biology is how plant cell interconnects with each other and recognizes signals from environmental cues. Many researchers in plant science declared that numerous surface receptors of cell containing extracellular leucine-rich repeats (eLRR) sense indications at the cellular level to respond to biotic or abiotic factors. Two classes of surface receptors families containing eLRRs in plants are receptor-like kinases (RLK) and receptor-like proteins (RLP), which are also known as pattern recognition receptors (PRR) (Zipfel C., 2014). General consensuses about the function of RLPs in plant species have been emphasized to play crucial roles in development stages and disease response (Tor M., et al, 2009).

Pathogen-associated molecular pattern (PAMP)-triggered immunity is activated through the recognition of microbe-derived patterns by PRRs (Albert I., et al. 2015). Well-studied PRRs include RLKs which have an intracellular kinase domain used to send the signal intracellularly, RLPs lack the kinase domain but the association of RLPs with SOBIR1-type adaptor kinases undergoes parallel functions in most of RLPs lacking cytoplasmic kinases domains for defense response. The association between SOBIR1 and RLPs occurs through leucine-rich repeat (LRR) domains by ionic interaction of their oppositely charged juxtamembrane domains and/or by helix–helix interactions of their transmembrane domains. Bimolecular equivalents of RLKs have similar function RLP/adaptor complexes by binding their ligands. The combination RLP/adaptor with ligands substitutes the formation of complex with co-receptor like BAK1/SERK1- type, which carries cytoplasmic domains. The process generates cytoplasmic signal output activation and phosphorylation (Gust A.A., and Felix G., 2014).

In many innate immunity related protein in organisms, the LRR containing domain is abundant. The eLRRs-RLP contains signal peptide (SP), N-terminus region (LRRNT) and C-terminus region (LRRCT) that include cysteine rich residues, LRR domains, island domain (IsD), linker and acidic domain (AD), transmembrane domain (TM), and cytoplasmic tail (CT). (Figure 1) (Jones D.A., Jones J.D.G., 1997).

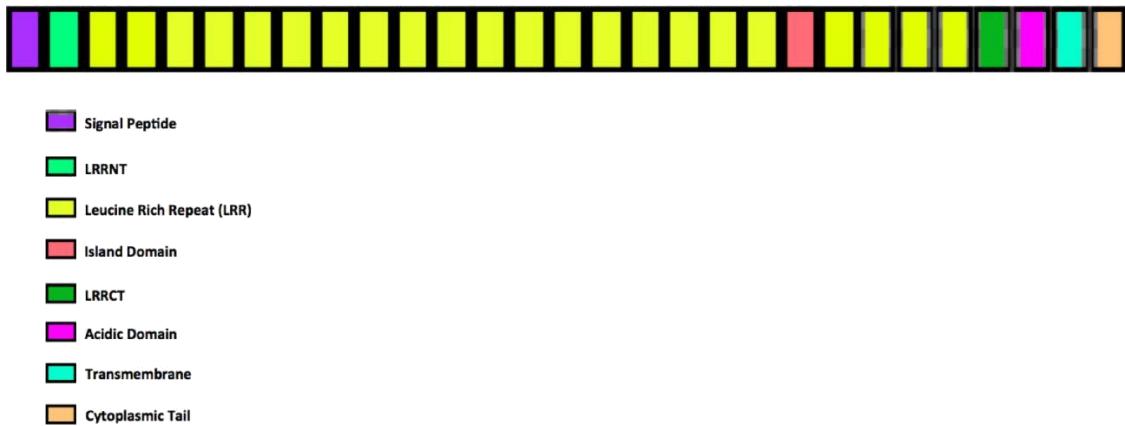

Figure 1. Structure of the various domains of typical RLPs.

Signal peptide in these two classes of proteins is responsible to target protein to plasma membrane. Jones D.A., Jones J.D.G. reported in 1997 that extracellular Leucine rich repeat are generated conserved motif plant specific LxxLxxLxLxxNxLt/sgxIpxxLG and LxxLxLxxN/CxL. Extracellular Leucine-rich repeats provide to mediate protein-protein interaction (Wang G., et al, 2010). Even if not all RLPs include an island domain, non-LRR island domain intervenes eLRR subdomains. Acidic domain function has not been clarified until now, however the acidic regions are thought as transactivation domains in most of transcription factors (Schwechheimer C., 1998). Proline-rich acidic domain may helps to the secondary structure of protein in plant and animal cells. Possessing a (G/S/T)XXX(G/S/T) motif in trans-membrane plays a critical role in intramolecular and intermolecular interactions between RLPs and other proteins such as RLK (Fritz-Laylin L.K., et al., 2005). Malectin, is isolated from *Xenopus laevis*, has a function as carbohydrate-binding domain such as lectins (Schallus T., et al., 2008). The Tyr-Xaa-Xaa-∅ (YXX∅) motif, which may help endocytosis mechanism, is a

tyrosine-based sorting signal in cytoplasmic tail, which is found in the several RLPs but not all (Wang G., et al. 2010). All kingdoms include malectin domains. The binding of two tandem malectins generates malectin-like domain. Many studies reported that malectin-like receptor like kinase contributes to defense response (Chen C.W., et al. 2014; Hok S., et al 2011) whereas malectin-like receptor like protein may require for developmental stage. AtRLP4 is malectin type of receptor like protein in Arabidopsis (Fritz-Laylin L.K., et al., 2005).

Virus-induced gene silencing (VIGS) is commonly preferred to prevent time-consuming, and thank to its ease of handling to engineering phenotypes (Lu, R., et al 2003). The advantages of the method are that partial sequences of gene is enough to silence gene, no required for transformation, easy and rapid, useful for forward and reverse genetics, and targeting multiple copies of gene in polyploidy plant (Senthil-Kumar, M., and Mysore, K.S., 2012). VIGS provides a powerful reverse genetic approach for post-transcriptional gene silencing in plant species by utilizing the biological function of the RNA (ribonucleic acid) defense mechanism. The accrued foreign double-strain RNA (dsRNA) in plant cell is recognized for degradation by the RNA defense (Ruiz, M.T., et al. 1988). VIGS vectors pTRV1 and pTRV2 expressing in the agrobacterium encode target sequences derived from the plant genome. The combinations of the expressed foreign RNAs increase the accumulation of dsRNA. The accumulated dsRNA are transferred into a RNA-induced silencing complex (RISC) to cleave into short interfering (siRNA) duplexes of the length of 21-24 nucleotides by dicer-like protein in plant cell (Dominique R., 2004; Buhrow, L.M., et al. 2016).

Disease losses in cotton are important issues for yield around world. Plantation of infested fields with susceptible cultivars and disease management are highly limited for pathogens (Davis, R. M., et al. 2006). The soil-borne fungal pathogen *Fusarium oxysporum* is colonized in vascular tissues and stunting, wilting, chlorosis and necrosis of leaves, and death cells in a wide variety of crops. This devastating disease influences adversely a large spectrum of economically valuable crops all over the world (Catanzariti, A.M., et al. 2015). Darling Downs had first discovered Fusarium wilt in 1993. Fusarium wilt has long been an important disease.

The *Arabidopsis* genome and rice genome have 57 and 90 RLPs, respectively (Fritz-Laylin L.K., et al. 2005). Although 66 of *P.trichocarpa* RLP have been clustered up to seven members, *P.trichocarpa* has totally 82 RLPs in genome (Petre, B., et al. 2014). 144 RLPs, including two AtRLP4-like proteins have been identified through a genome-wide analysis of resistance gene analogues in cotton (Chen J.Y., et al. 2015). One of the first identified RLPs involved in plant defense was Cf-9, which confers resistance to *Cladosporium fulvum*. In addition, and Cf-2, Cf-4, Cf-4E, Cf-5, and Cf-9B receptor-like proteins provide resistance abilities to same the fungus by recognizing different or identical *avr* genes (Dixon M.S., et al. 1996; Joosten M.H., et al. 1997; Panter S.N., et al. 2002). Cure1 detects of the parasitic Cuscuta to initiate plant defense in tomato (Fürst U., et al. 2016). The ethylene-inducing xylanase 1 (*EIX1*) and ethylene-inducing xylanase 2 (*EIX2*) function as a PRR for the fungus elicitor xylanase (Ron M. and Avni A., 2004). *HcrVf2* (homologue of the *C. fulvum* resistance genes of the Vf region) encodes a receptor-like protein, and has a function against *Venturia inaequalis*

for preventing apple scab disease (Belfanti E., et al. 2004). The *L. maculans* resistance gene 3 (*LepR3*) postulates resistance to the fungus *Leptosphaeria maculans* upon the recognition of the elicitor AVR-LM1 (Larkan, N. J., et al. 2013). RLP1 is a pattern recognition receptor for eMAX from *Xanthomonas* spp (Jehle A.K., et al. 2013). In Arabidopsis, RLP3 (*Fusarium oxysporum*), RLP23 (*Phytophthora infestans* and *Sclerotinia sclerotiorum*), RLP30 (*Scerotinia sclerotiorum* and bacteria), RLP42 (fungal endopolygalacturonases), RLP51 (resistance pathways), and RLP52 (*Erysiphe cichoracearum*) have resistance features. TaRLP1.1, considered to be induced by *Puccinia striiformis* f. sp. *Tritici* (Pst), was depicted as a significant stripe rust defense gene in wheat (Jiang Z., et al. 2013). The tomato immune receptor Ve1 and GbVe1 (G. barbadense) manage resistance to the fungus *Verticillium dahliae* (De Jonge R., et al. 2012; Zhang Z., et al. 2012). All of these examples highlight the importance of RLPs in plant defense response. In this thesis, I will use a combination of bioinformatics and gene functional analysis to identify and characterize cotton RLPs that may play an important role in defense against *Fusarium oxysporum*.

2. METHODS

2.1 Sequence Database Searches

The latest *G. arboreum* (A2_BGI), *G. raimondii* (D5_JGI), and *G. hirsutum* (AD1_NBI), protein sequences were downloaded from the cotton genome database (<https://www.cottongen.org>). The amino acid sequences of Arabidopsis RLPs were downloaded from the Arabidopsis Information Resource website (TAIR) (<http://www.arabidopsis.org>). To get the complete *G. arboreum*, *G. raimondii*, and *G. hirsutum* numbers of RLP proteins, the cotton whole genome sequences were queried with the Arabidopsis using the BLASTP program. All predicted cotton proteins were further screened for potential RLP protein using the HMMER server. Based on the HMMER's manual, the *E* value for the search of candidate protein was set to <0.1 (Finn R. D., et al. 2015).

2.2 Determination of Protein Domain Structure and pI Value

The InterProScan server was used to identify different protein domains (Hunter S. et al. 2009). Hidden Markov models (HMMs) from the PFAM suite (<http://pfam.wustl.edu>) were used to identify the presence of LRRs and other structural domains (Finn R.D., et al. 2016). Receptor-like protein motif search was conducted using SMART (Letunic I., et al. 2015). Isoelectronic point of RLPs was calculated by using the isoelectronic point calculator (IPC) server (Kozlowski L.P., 2016).

2.3 LRRs Domains Identification

The numbers of leucine-rich repeats were detected by using the LRRsearch webpage (A. Bej, 2014), LRRfinder software (Offord V., et al. 2010), and CDD: NCBI's conserved domain database (Marchler-Bauer A., et al. 2015). The following leucine rich repeats domain families were identified which are LRR_1 – leucine-rich repeat (PF00560), LRRNT – leucine-rich repeat N-terminal domain (PF01462), LRV - leucine-rich repeat variant (PF01816), LRRNT_2 - leucine-rich repeat N-terminal domain (PF08263), LRR_4 - leucine-rich repeat (2 copies) (PF12799), LRR_5 - leucine-rich repeat (6 copies) (PF13306), LRR_8 - leucine-rich repeat (PF13855), LRR_9 - leucine-rich repeat (PF14580), LRRCT - leucine-rich repeat C-terminal domain (PF01463), LRR_2 - leucine-rich repeat (PF07723), and LRR_3 - leucine-rich repeat (PF07725) (Magalhães D.M., et al, 2016).

2.4 Transmembrane and Signal Peptide Identification

The TMHMM website (<http://www.cbs.dtu.dk/services/TMHMM/>) hosted by the Center for Biological Sequence Analysis, Technical University of Denmark was used to predict transmembrane helices in proteins. The prediction of transmembrane helices in the protein sequences were conducted according to the default parameters of version 2.0 (Sonnhammer E.L., et al. 1998). The SignalP server was used to predict the existence and position of signal peptide cleavage sites in amino acid sequences of proteins (Petersen T.N., et al. 2011).

2.5 Orthologs Group in Cotton

The OrthoMCL applies the Markov Cluster (MCL) algorithm for clustering a set of protein sequences with complicated domain structures based on their sequence similarity. This database contained 116,536 ortholog groups clustered from 1,270,853 protein from 88 eukaryotic, 16 archaeal, and 34 bacterial genomes (<http://orthomcl.org/orthomcl/>). Retrieval proteins were performed by OrthoMCL webpage (Appendix A).

2.6 Multiple Sequence Alignment and Phylogenetic Analysis

In this study, several multiple sequence alignment approaches were performed to illuminate RLPs sequences. MUSCLE (Edgar, R.C., 2004) was used to align global homology group (<http://www.drive5.com/muscle>). MAFFT (Katoh K., and Standley D.M., 2013) was used to align the protein sequences for phylogenetic analysis (<http://mafft.cbrc.jp/>). The corresponding protein sequences imported into MEGA6 for multiple sequence alignment by ClustalW and phylogenetic analysis by using the Unweighted Pair Group Method with Arithmetic (UPGMA). The weighing matrix used for ClustalW alignment BLOSUM with the penalty of gap opening 10 and gap extension 0.2. (Tamura K., et al. 2013). Trees were visualized by using the Interactive Tree of Life webpage.

2.7 Plant Materials and Growth

Cotton (*Gossypium hirsutum*) Fibermax (FM) 9160B2F cultivar seeds, which are provided by Bayer Cropsciences at Lubbock, TX, were germinated in pots containing

Metro Mix 900 in a growth room at room temperature for 10 days with a 12h photoperiod until two cotyledon emerged.

2.8 Construction of VIGS Vectors

The cDNA of GhCLA1, Gh_A07G1586 (Gh_RLP23_1) and Gh_D07G1774 (Gh_RLP23_1), Gh_D07G1953 (GhRLP23_2), Gh_A11G2283 (GhRLP23_3A), Gh_D09G2477 (GhRLP23_3D), Gh_D01G0395 (AtRLP34), Gh_D11G2968 (AtRLP27), Gh_D05G3192 (AtRLP7), Gh_A03G0773 (GSO1), Gh_D04G1293 (AtRLP6), Gh_A12G0722 (AtRLP44), and Gh_D13G2467 (AtRLP9) cDNA was amplified by polymerase chain reaction (PCR) from induced cDNA of *G. hirsutum* by several different pathogens (Appendix B). Target amplicons, pTRV-RNA1, pYL156 (pTRV-RNA2) were digested with restriction enzymes EcoRI and KpnI. The digested amplicons were ligated into pYL156 (pTRV-RNA2) vector at 16°C overnight. The constructs were transformed into *E. coli* (MC1061) component cells, and plated onto LB media containing kanamycin (50µg/ml) antibiotic at 37°C overnight. Plasmid DNA was isolated from the transformed colonies through alkaline lysis method. Sanger sequencing was used to validate the insertion (Used primers are given in Table 7).

2.9 Agrobacterium-Mediated VIGS

Plasmids that were sequenced and found to carry the target insert were transformed into *Agrobacterium tumefaciens* (GV3101) by electroporation. Colonies were inoculated into LB medium containing gentamicin (50µg/ml) and kanamycin (50µg/ml) at 28°C for overnight. The cells were collected by centrifugation and re-suspended in infiltration Buffer (10 mM MgCl₂, 10 mM MES and 200 uM

acetosyringone). The Agrobacterium culture containing pTRV-RNA1 and pTRV-RNA2 or pTRV-GhGene was mixed at 1:1 ratio (final OD of 0.75 for each one). Mixture cultures inoculated into cotton stems with a needle syringe. The VIGS experiment was performed with more than 15 plants used for each construct.

2.10 *F. Oxysporum* Inoculation and Disease Index

Fusarium oxysporum was grown in potato dextrose broth (PDB) medium at room temperature for 6-7 days. The culture was centrifuged at 4,000 rpm for 10 minutes to collect the pellet. *F. oxysporum* conidial suspensions (1×10^7 spores.mL $^{-1}$) with 0.001% tween were inoculated into cotton stems by using a needle syringe less than 1 cm below the cotyledons into VIGS plants. The disease symptom was divided into 5 levels (level 0-4) and calculated using the formula $DI = (\sum (n \times \text{number of seedlings at level n})) / (4 \times \text{number of total seedlings} \times 100)$ (n refers the severity of the disease level of the plants). *Fusarium* inoculated plants were observed daily until 25 days post inoculation (dpi). Disease index indicates the infection ratio of a population.

3. RESULTS

3.1 Receptor-like Protein in Arabidopsis

3.1.1 Chromosomal Distribution of AtRLPs

57 receptor-like proteins were retrieved from Arabidopsis Genome database (www.arabidopsis.org) (Table 1). A chromosomal map tool was used to determine the distributions of AtRLPs genes on the *Arabidopsis* chromosomes with exception of AT1G54480 (AtRLP8/ RPP27) (Fig 2).
(<https://www.arabidopsis.org/jsp/ChromosomeMap/tool.jsp>).

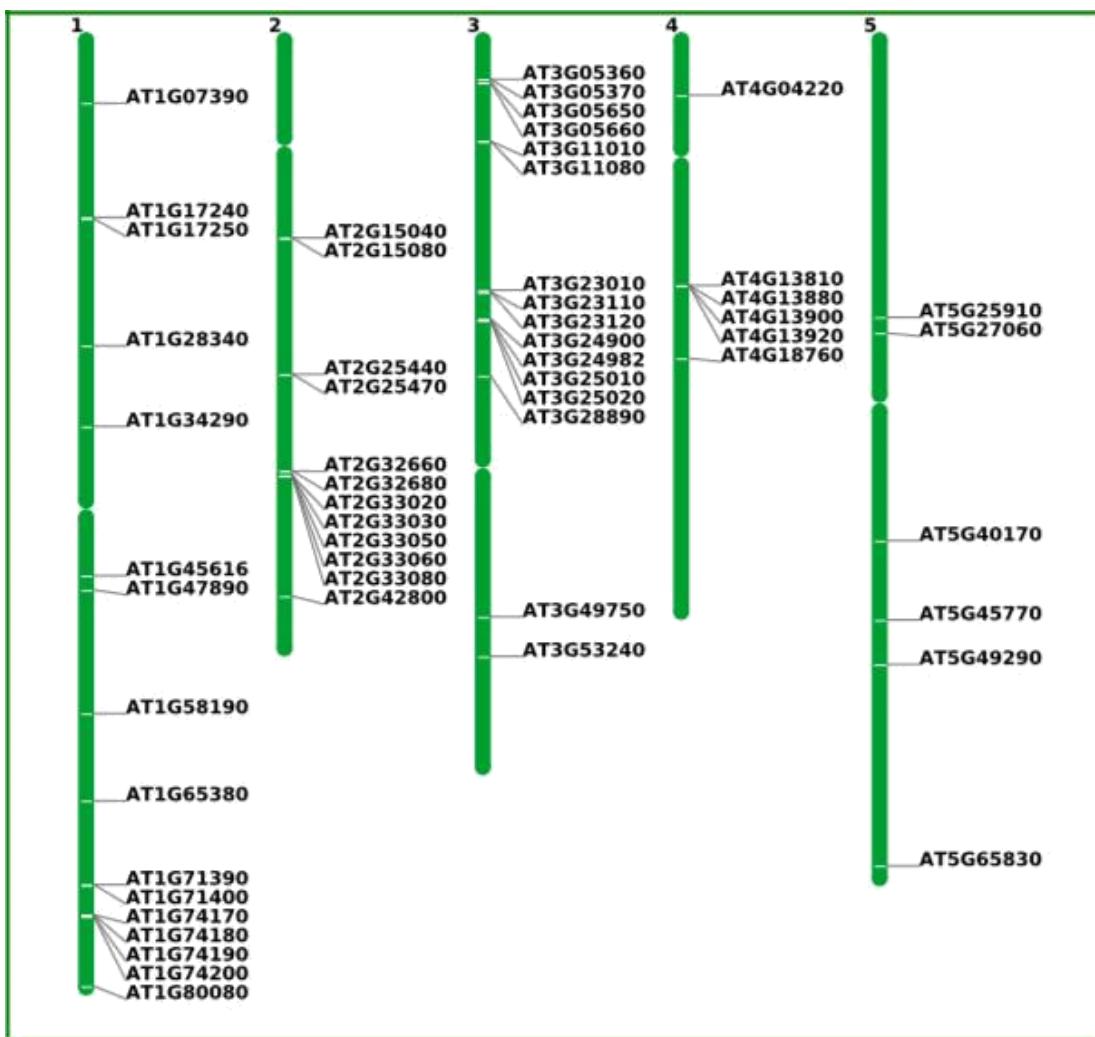

Figure 2. Representative *A. thaliana* RLPs chromosomal map

The receptor-like proteins (RLPs) in *Arabidopsis* are distributed across the five chromosomes. Most of the RLPs are located on chromosome1 in *Arabidopsis* genome. Chromosome 1 includes seventeen RLPs from AtRLP1 to AtRLP17; chromosome 2 includes twelve RLPs from AtRLP18 to AtRLP29; chromosome 3 includes sixteen RLPs from AtRLP30 to AtRLP45; chromosome 4 includes six RLPs from AtRLP46 to AtRLP51; chromosome 5 includes six RLPs from AtRLP52 to AtRLP57 (Fig2; Table1). AtRLP25 is the shortest of all RLPs whereas AtRLP1 is longest. The pI value of RLPs varies from 4.702 to 9.278. AtRLP47 has the lowest pI value whereas AtRLP55 has the highest.

3.2 Receptor-Like Protein in Cotton

3.2.1 Identification of RLPs in Cotton

The amino acid sequence of all *Arabidopsis* LRR-RLPs provided from the *Arabidopsis* genome database were used as queries to perform a BLASTp analysis against cotton the protein database to identify LRR-RLPs in *G. arboreum*, *G. raimondii*, and *G. hirsutum*. Retrieved protein sequences were uploaded to SMART, PFAM, STRING, and InterProScan, CDD from NCBI to annotate and validate the domain structure of proteins. A candidate LRR-RLP had to at least possess one LRR domain and a transmembrane domain. After eliminating of the unmatched sequences manually by using multiple sequence alignments with known receptor-like protein in the *Arabidopsis* database, 86 LRR-RLPs in *Gossypium arboreum*, 107 LRR-RLPs in *Gossypium raimondii*, and 151 LRR-RLPs in *G. hirsutum* were identified (Table 2).

Table 2. The number of RLPs in Cotton

Species	Receptor-like proteins	Malectin-like RLPs	Total
<i>A. Thaliana</i>	56	1	57
<i>G. Arboreum</i>	85	1	86
<i>G. Raimondii</i>	105	2	107
<i>G. Hirsutum</i>	145	6	151

The peptide length of retrieved LRR-RLPs ranged from 218-1083 amino acids in *A. thaliana*, 181-1125 amino acids in *G. arboreum*, 191-1176 amino acids in *G. raimondii*, and 193-1981 amino acids in *G. hirsutum*. The chromosome location, and the characteristics such as nucleic acid length, amino acid sequences length, protein weight, isoelectronic point, and the number of LRRs for each RLP was listed as detailed information. The number of GaLRR-RLPs, GrLRR-RLPs, and GhLRR-RLPs are approximately 1.50, 1.88, and 2.63 fold higher than the number of AtLRR-RLPs, respectively.

3.2.2 GaRLPs Biochemical Features and Chromosomal Distribution

The RLPs in *Gossypium arboreum* are distributed across the thirteen chromosomes. Most of RLPs are located on chromosome 12 in the genome (Fig 3).

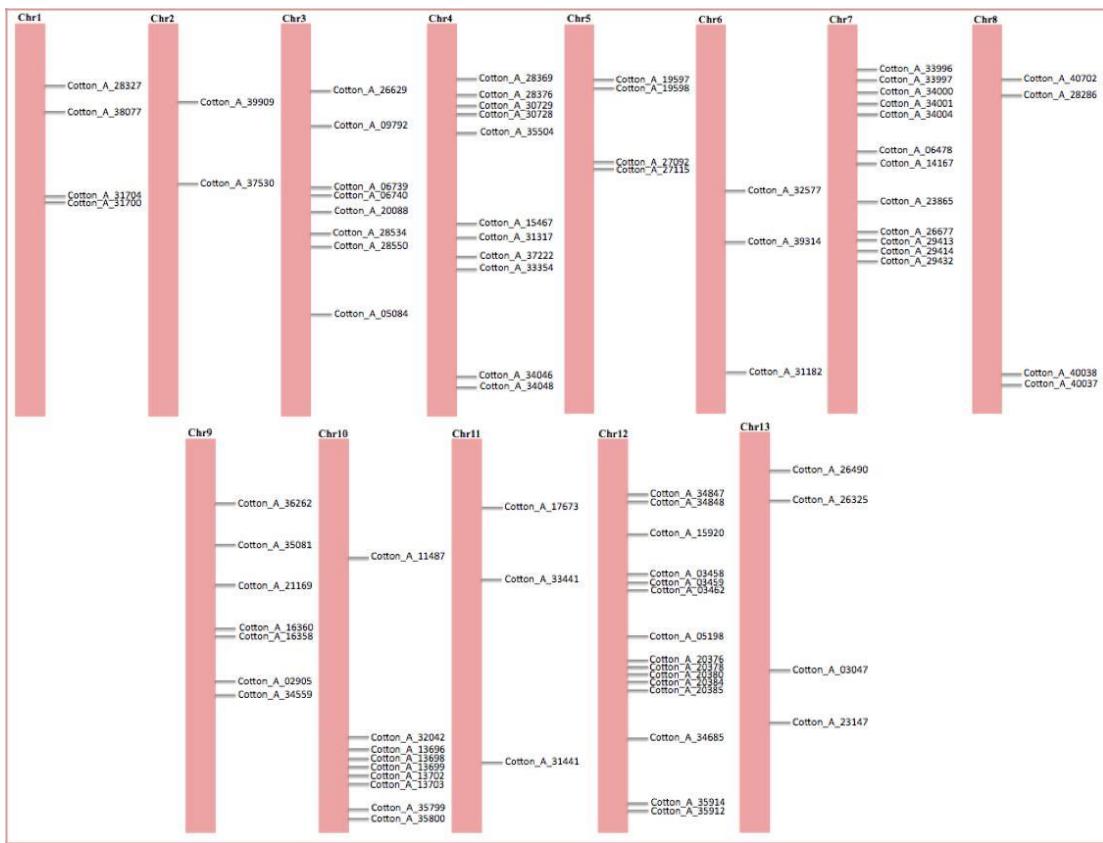

Figure 3. Representative *G. arboreum* RLPs chromosomal map

Chromosome 1 includes four RLPs which are Cotton_A_28327, Cotton_A_38077, Cotton_A_31704, and Cotton_A_31700; chromosome 2 includes two RLPs which are Cotton_A_39909 and Cotton_A_37530; chromosome 3 includes eight RLPs which are Cotton_A_09792, Cotton_A_06739, Cotton_A_06740, Cotton_A_20088, Cotton_A_28534, Cotton_A_28550, Cotton_A_26629, and Cotton_A_05084; chromosome 4 includes eleven Cotton_A_28369, Cotton_A_28376, Cotton_A_34046, Cotton_A_34048, Cotton_A_30729, Cotton_A_30728, Cotton_A_35504, Cotton_A_15467, Cotton_A_31317, Cotton_A_37222, and Cotton_A_33354;

chromosome 5 includes four RLPs which are Cotton_A_19597, Cotton_A_19598, Cotton_A_27092, and Cotton_A_27115; chromosome 6 includes three RLPs which are Cotton_A_32577, Cotton_A_39314, and Cotton_A_31182; chromosome 7 includes twelve RLPs which are Cotton_A_33996, Cotton_A_33997, Cotton_A_34000, Cotton_A_34001, Cotton_A_34004, Cotton_A_06478, Cotton_A_14167, Cotton_A_23865, Cotton_A_26677, Cotton_A_29413, Cotton_A_29414, and Cotton_A_29432; chromosome 8 includes four RLPs which are Cotton_A_40702, Cotton_A_28286, Cotton_A_40038, and Cotton_A_40037; chromosome 9 includes seven RLPs which are Cotton_A_36262, Cotton_A_35081, Cotton_A_21169, Cotton_A_16360, Cotton_A_16358, Cotton_A_02905, Cotton_A_34559; chromosome 10 includes nine RLPs which are Cotton_A_32042, Cotton_A_13696, Cotton_A_13698, Cotton_A_13699, Cotton_A_13702, Cotton_A_13703, Cotton_A_35799, Cotton_A_35800, and Cotton_A_11487; chromosome 11 includes three RLPs which are Cotton_A_31441, Cotton_A_17673, and Cotton_A_33441; chromosome 12 includes fifteen RLPs which are Cotton_A_34847, Cotton_A_34848, Cotton_A_15920, Cotton_A_03458, Cotton_A_03459, Cotton_A_03462, Cotton_A_05198, Cotton_A_20376, Cotton_A_20378, Cotton_A_20380, Cotton_A_20384, Cotton_A_20385, Cotton_A_34685, Cotton_A_35914, and Cotton_A_35912; chromosome 13 includes four RLPs which are Cotton_A_26490, Cotton_A_26325, Cotton_A_03047, and Cotton_A_23147 (Table 3).

3.2.3 GrRLPs Biochemical Features and Chromosomal Distribution

The RLPs in *Gossypium raimondii* are distributed across the thirteen chromosomes. Most of the RLPs are located on chromosome 2, chromosome 5, chromosome 7, and chromosome 9 in *Gossypium raimondii* genome (19, 15, 18, 15, respectively) (Fig 4).

Figure 4. Representative *G. raimondii* RLPs chromosomal map

Chromosome 1 includes four RLPs which are Gorai.001G203400.1, Gorai.001G223400.1, and Gorai.001G268900.1; chromosome 2 includes nineteen RLPs which are Gorai.002G039000.1, Gorai.002G040300.1, Gorai.002G052600.1, Gorai.002G052800.1, Gorai.002G052900.1, Gorai.002G053000.1,

Gorai.002G054900.1, Gorai.002G060300.1, Gorai.002G060400.1,
Gorai.002G060500.1, Gorai.002G060600.1, Gorai.002G060800.1,
Gorai.002G104100.1, Gorai.002G104200.1, Gorai.002G259400.1,
Gorai.002G259500.1, Gorai.002G262300.1, Gorai.002G264500.1, and
Gorai.002G264600.1; chromosome 3 includes one RLP which is Gorai.003G032400.1;
chromosome 4 includes seven RLPs which are Gorai.004G023200.1,
Gorai.004G023400.1, Gorai.004G023800.1, Gorai.004G028400.1,
Gorai.004G051800.1, Gorai.004G053700.1, and Gorai.004G054100.1; chromosome 5
includes fifteen RLPs which are Gorai.005G026300.1, Gorai.005G026400.1,
Gorai.005G026600.1, Gorai.005G028600.1, Gorai.005G028900.1,
Gorai.005G029100.1, Gorai.005G029200.1, Gorai.005G029300.1,
Gorai.005G029400.1, Gorai.005G031800.1, Gorai.005G031900.1,
Gorai.005G032000.1, Gorai.005G032100.1, Gorai.005G032200.1, and
Gorai.005G044400.1; chromosome 6 includes three RLPs which are
Gorai.006G056300.1, Gorai.006G087900.1, Gorai.006G184100.1; chromosome 7
includes eighteen RLPs which are Gorai.007G226700.1, Gorai.007G328800.1,
Gorai.007G281100.1, Gorai.007G289600.1, Gorai.007G324500.1,
Gorai.007G324800.1, Gorai.007G327300.1, Gorai.007G327600.1,
Gorai.007G327700.1, Gorai.007G328000.1, Gorai.007G328200.1,
Gorai.007G328500.1, Gorai.007G328600.1, Gorai.007G328900.1,
Gorai.007G329100.1, Gorai.007G329300.1, Gorai.007G329400.1, and
Gorai.007G339000.1; chromosome 8 includes one RLP which is Gorai.008G086100.1;

chromosome 9 includes fifteen RLPs which are Gorai.009G010400.1, Gorai.009G014000.1, Gorai.009G367500.1, Gorai.009G367700.1, Gorai.009G367800.1, Gorai.009G444200.1, Gorai.009G444400.1, Gorai.009G447900.1, Gorai.009G448000.1, Gorai.009G448100.1, Gorai.009G448200.1, Gorai.009G448500.1, Gorai.009G448600.1, Gorai.009G448900.1, and Gorai.009G449100.1; chromosome 10 includes five RLPs which are Gorai.010G071900.1, Gorai.010G160400.1, Gorai.010G203200.1, Gorai.010G228600.1, and Gorai.010G228800.1; chromosome 11 includes ten RLPs which are Gorai.011G038000.1, Gorai.011G138000.1, Gorai.011G138100.1, Gorai.011G138200.1, Gorai.011G138300.1, Gorai.011G029600.1, Gorai.011G257100.1, Gorai.011G045500.1, Gorai.011G154100.1, and Gorai.011G155400.1; chromosome 12 includes five RLPs which are Gorai.012G117000.1, Gorai.012G117200.1, Gorai.012G068800.1, Gorai.012G117100.1, and Gorai.012G134600.1; chromosome 13 includes five RLPs which are Gorai.013G069300.1, Gorai.013G174000.1, Gorai.013G236800.1, Gorai.013G237000.1, and Gorai.013G237100.1 (Table 4).

3.2.4 GhRLPs Biochemical Features and Chromosomal Distribution

Phylogenetic analysis has conducted that *G. hirsutum* ($4n = 4x = 52$; AADD genome) is a hybrid of two diploid species, *G. arboreum* ($2n = 2x = 26$; AA genome) and *G. raimondii* ($2n = 2x = 26$; DD genome). The A- subgenome has 57 RLPs on the 13 chromosomes. The B sub-genome has The D- subgenome has 89 RLPs on the 13 chromosomes. 5 RLPs, which are named as Gh_Sca006073G01 (scaffold6073: 676-3840+) that encodes 915 amino acids, Gh_Sca007858G02 (scaffold7858: 4481-5671-) that encodes 396 amino acids, Gh_Sca012881G01 (scaffold12881: 156-1679+) that encodes 507 amino acids, Gh_Sca024892G01 (scaffold24892: 442-1224-) that encodes 260 amino acids, Gh_Sca042904G01 (scaffold42904: 24-833-) that encodes 269 amino acids, are not well annotated (Fig 5; Fig 6).

Figure 5. Representative *G. hirsutum* A-subgenome RLPs chromosomal map

Figure 6. Representative *G. hirsutum* D-subgenome RLPs chromosomal map

On the A- subgenome in *Gossypium hirsutum*, chromosome 1 includes six RLPs which are Gh_A01G0363, Gh_A01G0383, Gh_A01G0384, Gh_A01G1976, Gh_A01G1977, and Gh_A01G2062; chromosome 2 includes seven RLPs which are Gh_A02G0194, Gh_A02G0195, Gh_A02G0215, Gh_A02G0704, Gh_A02G0705, Gh_A02G1220, and Gh_A02G1437; chromosome 3 includes three RLPs which are Gh_A03G0525, Gh_A03G0773, and Gh_A03G0841; chromosome 4 includes eight RLPs which are Gh_A04G0061, Gh_A04G0063, Gh_A04G0345, Gh_A04G0346,

Gh_A04G0347, Gh_A04G0799, Gh_A04G0802, and Gh_A04G0939; chromosome 5 includes six RLPs which are Gh_A05G0030, Gh_A05G0060, Gh_A05G3063, Gh_A05G3366, Gh_A05G3373, and Gh_A05G3868; chromosome 6 includes three RLPs which are Gh_A06G1562, Gh_A06G1649, and Gh_A06G2050; chromosome 7 includes two RLPs which are Gh_A07G1586 and Gh_A07G1749; chromosome 8 includes two RLPs which are Gh_A08G0171 and Gh_A08G1930; chromosome 9 includes two RLPs which are Gh_A09G0698 and Gh_A09G2492; chromosome 10 includes eight RLPs which are Gh_A10G0328, Gh_A10G0389, Gh_A10G1129, Gh_A10G1130, Gh_A10G1219, Gh_A10G1261, Gh_A10G1945, and Gh_A10G2219; chromosome 11 includes five RLPs which are Gh_A11G0629, Gh_A11G1919, Gh_A11G2279, Gh_A11G2283, and Gh_A11G2353; chromosome 12 includes two RLPs which are Gh_A12G0462 and Gh_A12G0722; chromosome 13 includes three RLPs which are Gh_A13G0521, Gh_A13G1285, and Gh_A13G2320 (Table 5).

On the D- subgenome in *Gossypium hirsutum*, chromosome 1 includes ten RLPs which are Gh_D01G0393, Gh_D01G0395, Gh_D01G0772, Gh_D01G2187, Gh_D01G2188, Gh_D01G2217, Gh_D01G2236, Gh_D01G2319, Gh_D01G2320, and Gh_D01G2332; chromosome 2 includes twelve RLPs which are Gh_D02G0234, Gh_D02G0236, Gh_D02G0237, Gh_D02G0257, Gh_D02G0258, Gh_D02G0259, Gh_D02G0277, Gh_D02G0280, Gh_D02G0281, Gh_D02G0282, Gh_D02G0749, and Gh_D02G1154; chromosome 3 includes two RLPs which are Gh_D03G0283 and Gh_D03G0505; chromosome 4 includes six RLPs which are Gh_D04G0212, Gh_D04G0581, Gh_D04G1292, Gh_D04G1293, Gh_D04G1294, and Gh_D04G1454;

chromosome 5 includes fourteen RLPs which are Gh_D05G0117, Gh_D05G1174, Gh_D05G3192, Gh_D05G3300, Gh_D05G3622, Gh_D05G3624, Gh_D05G3625, Gh_D05G3626, Gh_D05G3628, Gh_D05G3663, Gh_D05G3664, Gh_D05G3666, Gh_D05G3668, and Gh_D05G3670; chromosome 6 includes five RLPs which are Gh_D06G0603, Gh_D06G1447, Gh_D06G2016, Gh_D06G2019, and Gh_D06G2021; chromosome 7 includes three RLPs which are Gh_D07G0874, Gh_D07G1774, and Gh_D07G1953; chromosome 8 includes eight RLPs which are Gh_D08G0203, Gh_D08G0204, Gh_D08G0207, Gh_D08G0249, Gh_D08G0250, Gh_D08G0480, Gh_D08G0482, and Gh_D08G2296; chromosome 9 includes three RLPs which are Gh_D09G0711, Gh_D09G1576, and Gh_D09G2477; chromosome 10 includes eight RLPs which are Gh_D10G0253, Gh_D10G0334, Gh_D10G0404, Gh_D10G1221, Gh_D10G1222, Gh_D10G1277, Gh_D10G1381, and Gh_D10G1575; chromosome 11 includes twelve RLPs which are Gh_D11G0740, Gh_D11G2056, Gh_D11G2590, Gh_D11G2599, Gh_D11G2900, Gh_D11G2968, Gh_D11G2991, Gh_D11G2997, Gh_D11G2999, Gh_D11G3000, Gh_D11G3001, and Gh_D11G3383; chromosome 12 includes two RLPs which are Gh_D12G0464 and Gh_D12G0745; chromosome 13 includes four RLPs which are Gh_D13G1586, Gh_D13G2135, Gh_D13G2467, and Gh_D13G2468 (Table 5).

Table 5. The list of GhRLPs

3.3 Distribution of LRRs in *Arabidopsis* and Cotton

A RLP includes leucine-rich repeats motifs such as plant specific LxxLxxLxLxxNxLt/sgxIpxxLG and LxxLxLxxN/CxL residues and cysteine-rich LRR (LRRNT, and LRRCT). The number of LRRs in plant RLPs varies from 4 to 40 in plants depending on the length of peptides. All RLPs were divided into eight categories based on the number of LRRs the RLPs possessed in intervals of five (Table 6)

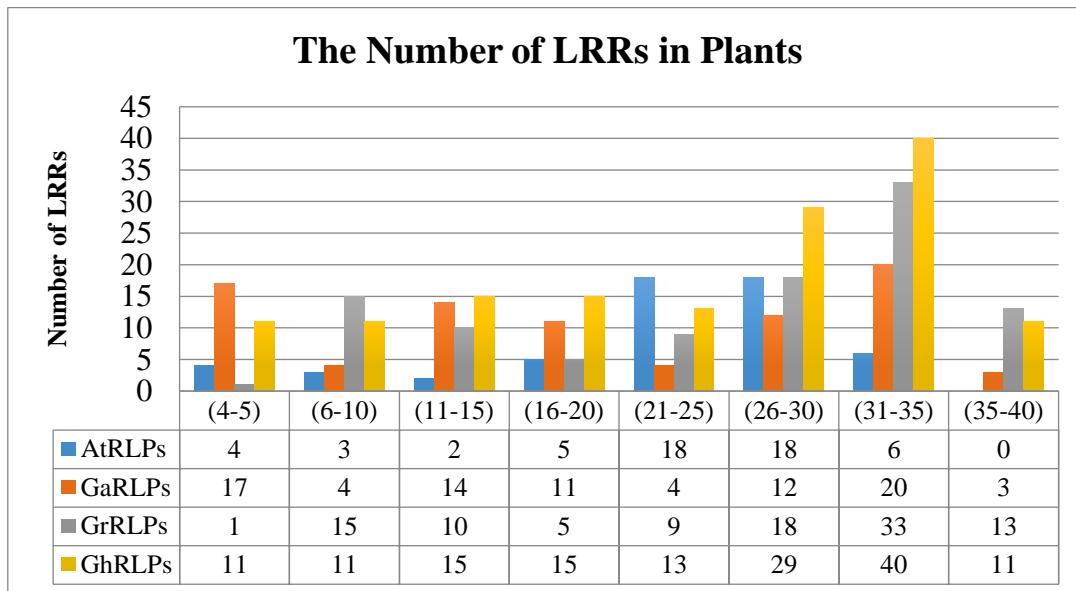

Table 6. Categorized LRRs in plants

The lowest number of LRRs containing RLPs in *Arabidopsis thaliana* was in the 11-15 intervals, whereas the highest number of LRRs was in the 21-25 and 26-30 intervals. The lowest number of LRRs containing RLPs in *Gossypium arboreum* was in the 35-40 intervals, whereas the highest number of LRRs was in the 31-35 intervals. The lowest number of LRRs containing RLPs in *Gossypium raimondii* was in the 4-5 intervals, whereas the highest number of LRRs was in the 31-35 intervals. The lowest

number of LRRs containing RLPs in *Gossypium hirsutum* was in the 4-5, 6-10, and 36-40 intervals, whereas the highest number of LRRs was in the 31-35 intervals.

3.4 Classifications and Phylogenetic Analysis of RLPs

3.4.1 OrthoMCL Analysis in Cotton

Most of the genes in tetraploid cotton have evolved from duplication events, which provide new gain-function or lost-function. However, these homologs may not be clustered with true homologs in other species. Subsequently, complicated domain structures of many proteins beclouds exactly clustering protein families and sharing similar domains, which involve in conservative motifs, in proteins cause of cluster mistakenly in many protein families. A third challenge in clustering orthologs result from uncompleted genome sequences (Li., L. et al. 2003).

The inflation value is a crucial parameter in MCL algorithm, which regulates the cluster granularity. A higher inflation value indicates higher cluster granularity. The final output from MCL analysis illustrates at least two species clusters containing sequences ID of orthologs (Li., L. et al. 2003).

Investigating the *G. arboreum* RLPs against the OrthoMCL database revealed that they clustered into 12 different orthologs. 35 GaRLPs belong to the OG5_130149 ortholog cluster, 20 GaRLPs belong to the OG5_134835 ortholog cluster, 15 GaRLPs belong to the OG5_164541 ortholog cluster, three GaRLPs belong to the OG5_164541 ortholog cluster, three GaRLPs belong to the OG5_128518 ortholog cluster, two GaRLPs belong to the OG5_212573 ortholog cluster, two GaRLPs belong to the OG5_244942 ortholog cluster, one GaRLP belongs to the OG5_136779 ortholog cluster,

one GaRLP belong to the OG5_189973 ortholog cluster, one GaRLP belongs to the OG_170335 ortholog cluster, one GaRLP belongs to the OG5_190449 ortholog cluster, one GaRLP belongs to the OG5_159729 ortholog cluster, and two GaRLPs did not cluster to any ortholog group.

Investigating the *G. raimondii* RLPs against the OrthoMCL database revealed that they clustered into nine different orthologs. 69 GrRLPs belong to the OG5_130149 ortholog cluster, 20 GrRLPs belong to the OG5_159698 ortholog cluster, four GrRLPs belong to the OG5_128518 ortholog cluster, three GrRLPs belong to the OG5_164541 ortholog cluster, two GrRLPs belong to the OG5_170335 ortholog cluster, two RLPs belong to the OG5_177950 ortholog cluster, two GrRLPs belong to the OG5_134835 ortholog cluster, one GrRLP belongs to the OG5_159729 ortholog cluster, one GrRLP belongs to the OG5_212573 ortholog cluster, and three of them did not cluster to any ortholog group.

Investigating the *G. hirsutum* RLPs against the OrthoMCL database revealed that they clustered into 14 different orthologs. 71 GhRLPs belong to the OG5_130149 ortholog cluster, 25 GhRLPs belong to the OG5_159698 ortholog cluster, 20 GhRLPs belong to the OG5_134835 ortholog cluster, seven GhRLPs belong to the OG5_164541 ortholog cluster, six GhRLPs belong to the OG5_128518 ortholog cluster, four GhRLPs belong to the OG5_177950 ortholog cluster, four GhRLPs belong to the OG5_170335 ortholog cluster, three GhRLPs belong to the OG5_244942 ortholog cluster, two GhRLPs belong to the OG5_190826 ortholog cluster, two GhRLPs belong to the OG5_189973 ortholog cluster, two GhRLPs belong to the OG5_188400 ortholog cluster,

two GhRLPs belong to the OG5_159729 ortholog cluster, one GhRLP belongs to the OG5_212573 ortholog cluster, one GhRLP belongs to the OG5_127136 ortholog cluster, and one of them did not cluster with any ortholog group (APPENDIX D).

3.4.2 Determination of Conserved Motifs in RLPs

The extracellular LRR-RLPs were divided into several domains named between A to G. An alterable tandem repeats indicated in the LRR domain C1 and linker domain C2. On the other hand, the LRR containing C3 domain and the linker domain D were conserved. For this reason, the C3 and D domains were preferred to perform the phylogenetic analysis (Fig 7) (Fritz-Laylin L.K., et al. 2005; Petre, B., et al 2014).

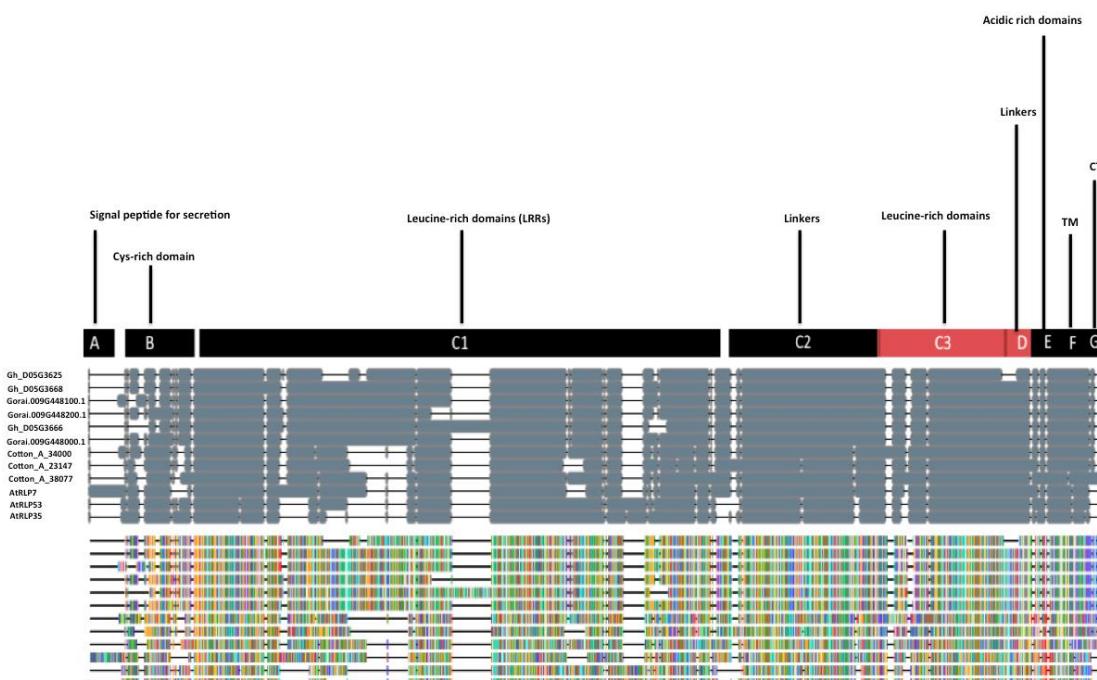

Figure 7. Conserved domain structure of RLPs (A-G)

3.4.3 Phylogenetic Trees for Four Species

3.4.3.1 Arabidopsis RLPs Phylogenetic Analysis

Arabidopsis RLPs were aligned via ClustalW algorithm and a rooted phylogenetic tree with branch length (UPGMA) was built. The tree was visualized by using the Interactive Tree of Life version 3.4.3 and the RLPs were divided into eight groups. Group I was marked in red and was further divided in two subgroups: dashed red line subgroup, which includes six RLPs descending from AtRLP6/7 and solid red line subgroup which includes nine RLPs descending from AtRLP52. Group II was marked in orange and includes thirteen RLPs descending from AtRLP54. Group III is in yellow and includes seven RLPs. Group IV is in green and includes AtRLP2 and AtRLP3, which are close paralogs. Light purple color represents group V and includes AtRLP44 and AtRLP57, which are close paralogs too. Group VI in blue includes eleven RLPs descending from AtRLP17. Group VII in purple includes AtRLP51 and AtRLP55, which are close paralogs and finally group VIII marked with light green includes AtRLP4, which encodes malectin-like RLP (Fig 8).

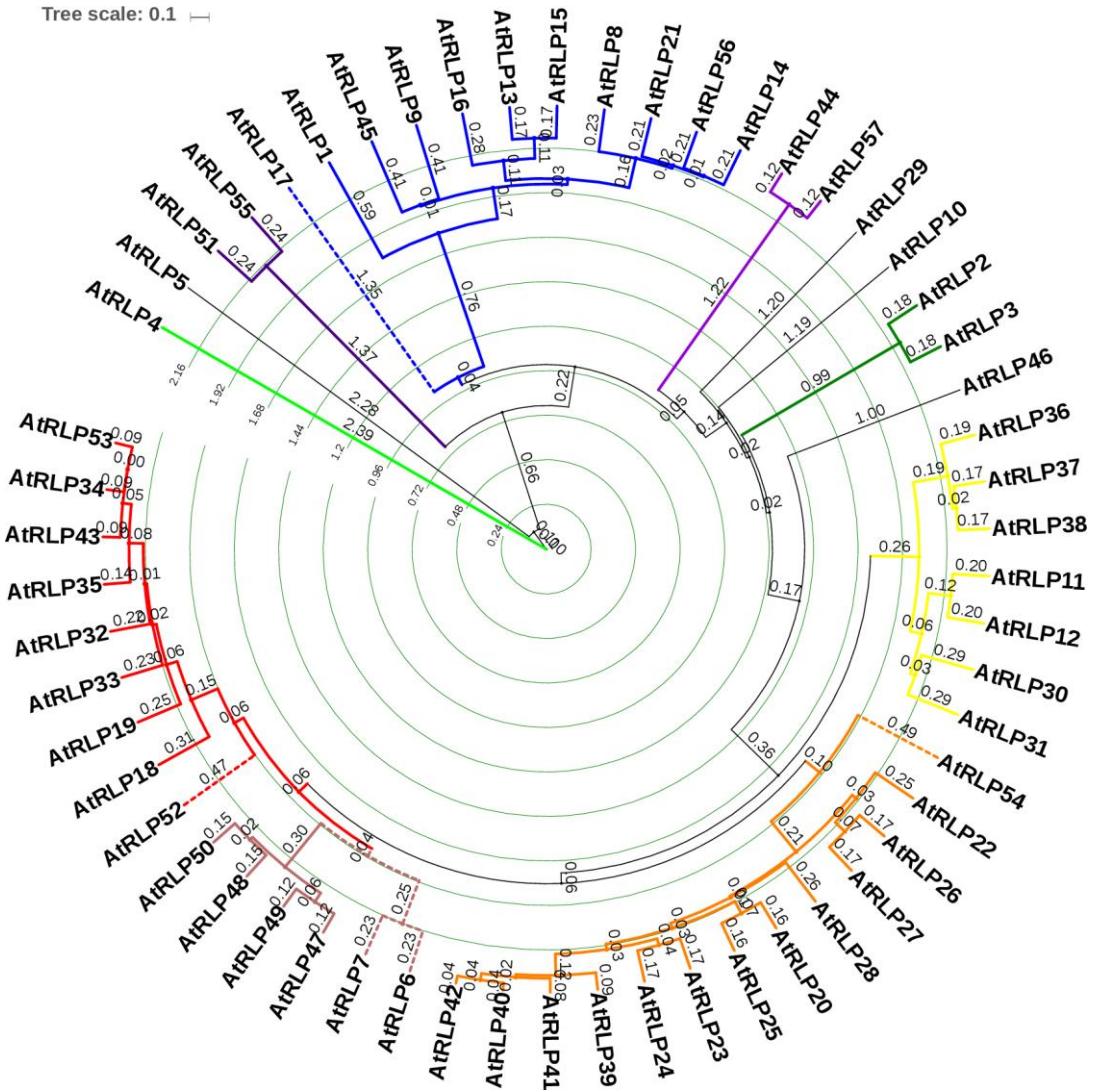

Figure 8. Arabidopsis Receptor-like protein tree

3.4.3.2 *G. arboreum* RLPs Phylogenetic Analysis

G. arboreum RLPs were aligned via ClustalW algorithm and a rooted phylogenetic tree with branch length (UPGMA) was built and analyzed as before. Group I in red is subdivided into two subgroups: dashed red lines subgroup including ten RLPs,

descending from Cotton_A_13702, and solid red line subgroup including eleven RLPs descending from Cotton_A_39909. Group II in orange includes nineteen RLPs descending from Cotton_A_26490. Group III is indicated in yellow and includes thirty-nine RLPs descending from Cotton_A_31182 and Cotton_A_06478, which are close paralogs. Group IV in green includes 3 RLPs, descending from Cotton_A_31317. Group V in blue includes three RLPs, descending from Cotton_A_32042 (Fig 9).

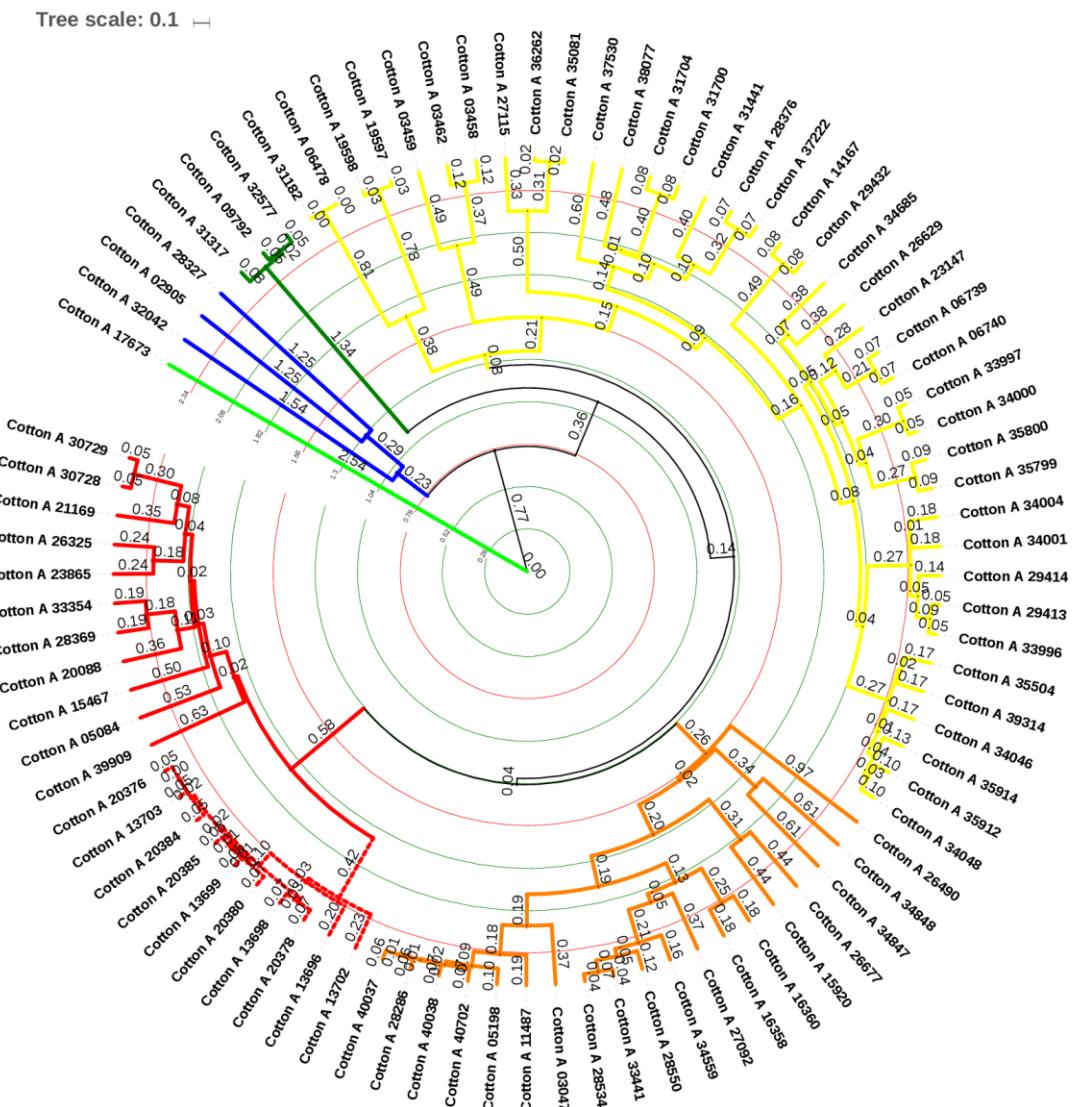

Figure 9. *Gossypium arboreum* Receptor-like protein tree

3.4.3.3 *G. raimondii* RLPs Phylogenetic Analysis

G. raimondii RLPs were aligned via ClustalW algorithm for multiple sequences alignment and a rooted phylogenetic tree with branch length (UPGMA) was built and analyzed as above. Group I indicated in red includes forty-seven RLPs descending from Gorai.002G039000.1 and Group II indicated in orange includes nine RLPs descending from Gorai.012G117000.1 and Gorai.012G117100.1. Group III in yellow includes twelve RLPs descending from Goria.011G154100.1 and Goria.011G155400.1. Group IV in green includes twenty-five RLPs descending from Goria.013G069300.1 and Goria.012G134600.1. Group V in blue includes three RLPs descending from Goria.011G045500.1. Group VI in purple includes three RLPs descending from Goria.007G226700.1. Group VII in light green is composed of two RLPs, Goria.011G029600.1 and Goria.006G087900.1, which encode malectin-like receptor like protein (Fig10).

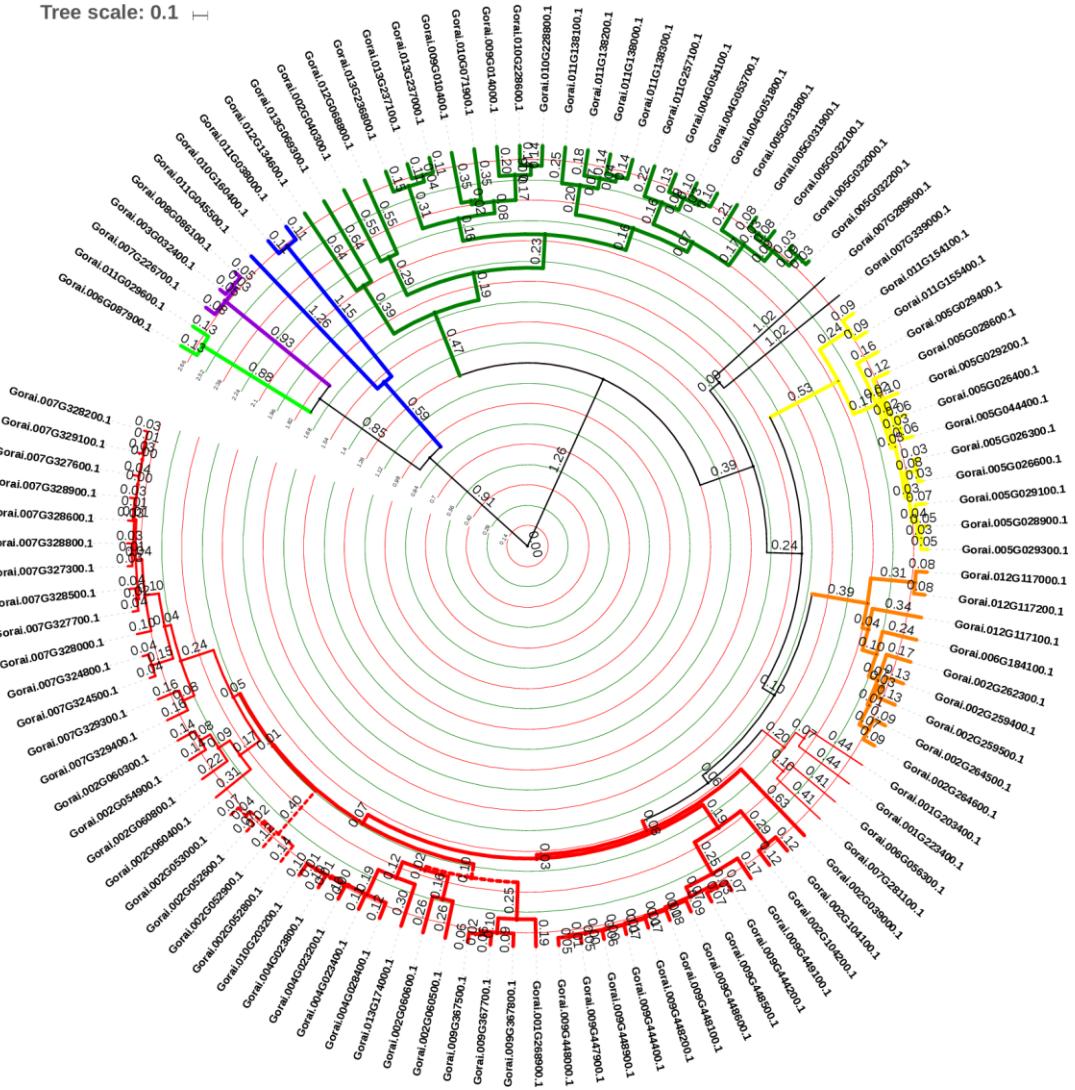

Figure 10. *Gossypium raimondii* Receptor-like protein tree

3.4.3.4 *G. hirsutum* RLPs Phylogenetic Analysis

G. hirsutum RLPs were also aligned via ClustalW and the rooted phylogenetic tree was visualized by using the Interactive Tree of Life version 3.4.3. Group I indicating red includes seventy-five RLPs descending from dashed-red –line.

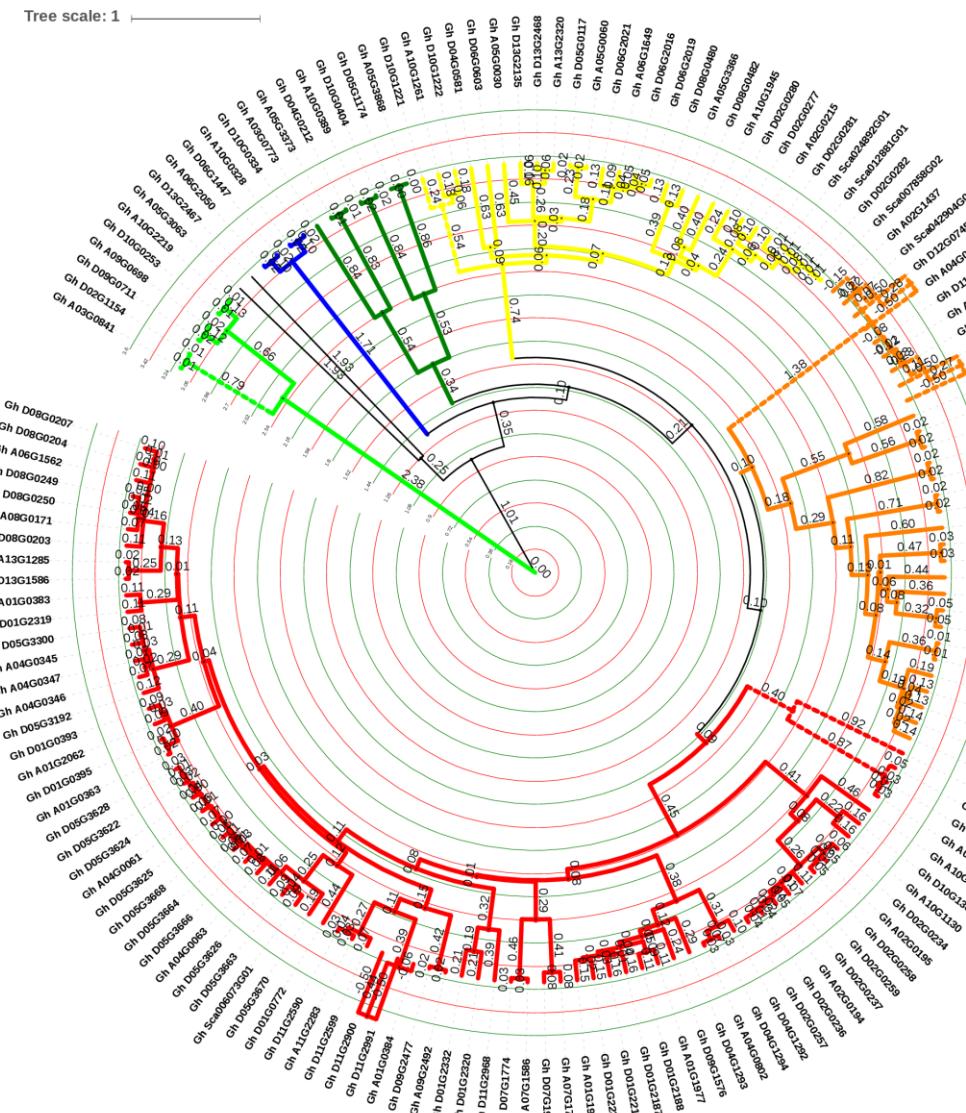

Figure 11. *Gossypium hirsutum* Receptor-like protein tree

Group II in orange includes thirty RLPs and group III in yellow includes twenty-seven 27 RLPs. Group IV in green includes seven RLPs descending from GhA03G0773. Group V in blue includes four RLPs, which are close homologs. Group VI in light green includes six malectin-like RLPs (Fig 11).

3.4.3.5 *Gossypium* spp. and *Arabidopsis* RLPs Phylogenetic Analysis

Plant RLPs were also aligned via ClustalW and the rooted phylogenetic tree was visualized by using the Interactive Tree of Life version 3.4.3 (Fig 8). The phylogenetic analysis was divided into 10 major clusters based on *Arabidopsis* RLPs distribution with sequences similarities. Group I indicating red includes two hundreds eight RLPs including 35 AtRLPs. Group II indicating orange includes one hundred twenty two RLPs descending from AtRLP2 and AtRLP3, which are close homolog. . Group III indicating yellow includes five RLPs descending from AtRLP46. . Group IV indicating green includes fifteen RLPs descending from AtRLP44 and AtRLP57, which are close homolog. . Group V indicating blue includes ten RLPs descending from AtRLP4. . Group VI indicating purple includes three RLPs descending from AtRLP10. Group VII indicating light purple includes three RLPs descending from AtRLP16. Group VIII indicating brown includes nine RLPs descending from AtRLP51 and AtRLP55, which are close homolog. Group IX indicating light green includes five RLPs descending from AtRLP29. Group X indicating gray includes five RLPs descending from AtRLP17 (Fig 12).

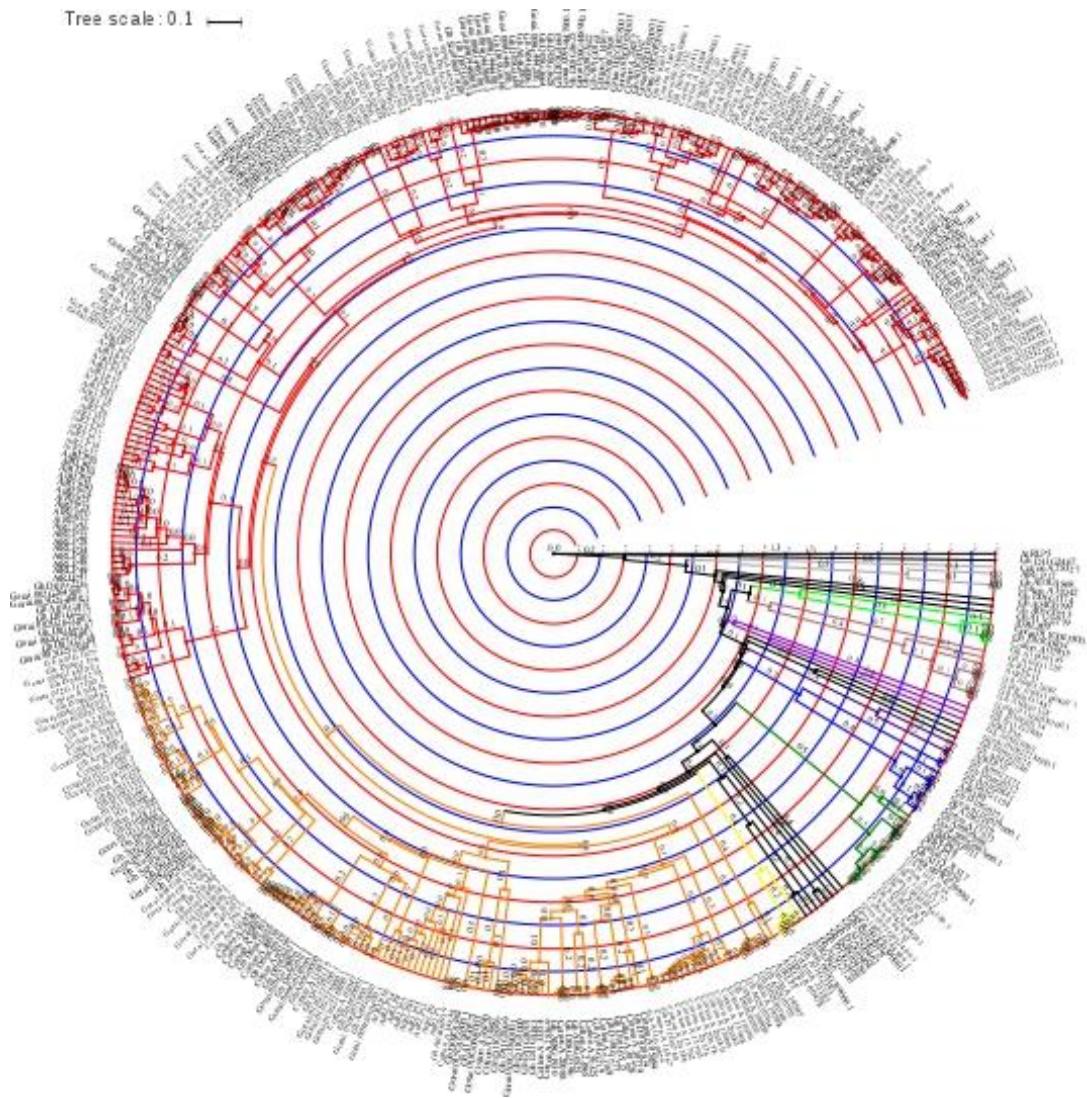

Figure 12. Distribution of all RLPs in phylogenetic tree

Most *Arabidopsis* RLPs are located in the red and orange clusters. Phylogenetic tree analysis with other plant LRR-RLPs suggested that cotton LRR-RLPs are likely evolved independently and clustered together.

3.5 RLPs Evolves Independently and Rapidly

Evolution processes through divergent alternations of genes, proteins, and phenotypic changes in time (Soskine M. and Tawfik D.S., 2010). Some species evolve convergently in distance relative taxa with identical selection process (Hoy, R. R., 2012). Because of the spread of adaptive phenotypic convergence in nature, some gene families might be useful to peruse evolution at the sequence level (Zhang, J. Z. & Kumar, S., 1997). Polyploidy plays a critical role in genome evolution. One of the critical questions in plant science and crop breeding is to understand how plants evolved through genome evolution mechanisms. Loss of functions, gain of functions, gene movement, and chromosomal structural changes cause diploidization after whole or partial genome duplication. *Gossypium hirsutum* is a hybrid of its antecedent A and D diploid progenitors. The polyploidization and hybridization of antecedent diploid genomes provide that cotton is a significant model organism for polyploid genome evolution studies (Rong, J., et al. 2010).

The diploid genomes of *G. arboreum* and *G. raimondii* include 86 and 107 RLPs. 20 RLPs in both are single-copy genes. They have mostly identical DNA sequences with exception of point mutations. 20 RLPs in *G. arboreum* genome are utterly different than *G. raimondii* RLPs, and 18 RLPs in *G. raimondii* genome are also species-specific genes, which are called “Singletons”. Furthermore, 46 RLPs in *G. arboreum* and 69 RLPs in *G. raimondii* create different numbers of cluster within each other. Each cluster includes at least one or more gene(s) with other species (Appendix C).

G. hirsutum is allotetraploid cotton and includes 151 RLPs. 16 RLPs in *G. hirsutum* genome are single-copy genes with *G. arboreum* RLPs. They have mostly identical DNA sequences with exception of point mutations. 38 RLPs in *G. hirsutum* genome are utterly different than *G. arboreum* RLPs, and 24 RLPs in *G. arboreum* genome are also species-specific genes, which are called “Singletons”. Furthermore, 97 RLPs in *G. hirsutum* and 46 RLPs in *G. arboreum* create different numbers of clusters within each other. Each cluster includes at least one or more gene(s) with other species (Appendix C).

G. hirsutum is allotetraploid cotton and includes 151 RLPs. 21 RLPs in *G. hirsutum* genome are single-copy genes with *G. raimondii* RLPs. They have mostly identical DNA sequences with exception of point mutations. 34 RLPs in *G. hirsutum* genome are utterly different from *G. raimondii* RLPs, and 19 RLPs in *G. raimondii* genome are also species-specific genes, which are called “Singletons”. Furthermore, 96 RLPs in *G. hirsutum* and 67 RLPs in *G. raimondii* create different numbers of clusters within each other. Each cluster includes at least one or more gene(s) with other species (Appendix C).

These fundings suggested that *Gossypium* ssp. evolved convergently and divergently through evolutionary mechanisms such as specification, hybridization, and polyloidy (Appendix D).

3.6 Cloning Receptor-Like Proteins for VIGS

3.6.1 Determination of Candidate RLPs from GhRLPs

Candidate cotton RLPs were chosen based on homology to well-studied RLPs on Arabidopsis and by comparing them through phylogenetic tree analysis. At the amino acid level, blast analysis against the *Gossypium* protein database illustrated the presence of cotton Gh_A07G1586 (Gh_RLP23_1) as the closest ortholog to AtRLP23 with 33.7% identity and 47.4% similarity. Other orthologs for AtRLP23 include Gh_D07G1774 (Gh_RLP23_1) with 34.2% identity and 48.6% similarity, Gh_D07G1953 (GhRLP23_2) with 34.8% identity and 49.0% similarity, Gh_A11G2283 (GhRLP23_3A) with 33.4% identity and 48.4% similarity and Gh_D09G2477 (GhRLP23_3D) with 33.0% identity and 46.0% similarity. Gh_D01G0395 is the ortholog of AtRLP34 with 10.3 % identity and 13.8% similarity and Gh_D11G2968 is the ortholog of AtRLP27 with 18.6% identity and 26.9 similarity. Furthermore, Gh_D05G3192 is the ortholog of AtRLP7 (34.8% identity and 50.9% similarity), Gh_A03G0773 is the ortholog of AtGSO1 (35.9% identity and 48.1% similarity), Gh_D04G1293 is the ortholog of AtRLP6 (34 % identity and 49.3% similarity), Gh_A12G0722 is the ortholog of AtRLP44 (73.4% identity and 83.2% similarity) and Gh_D13G2467 is the ortholog of AtRLP9 (13.6% identity and 21.2% similarity) (Appendix E). The coding DNA sequences of candidate RLPs were retrieved from the *Gossypium* cDNA database to design primers for VIGS using Primer3web version 4.0.0 webpage (Primers are provided below Table 7).

Table 7. Used primers in this study

3.6.2 Silencing of GhRLPs by Agrobacterium-Mediated VIGS

Virus Induced Gene Silencing (VIGS) approach is a very effective tool for the investigation of gene function in many crop species (Xiquan G. et al. 2011). We used GhCLA1 gene, which encodes a 1-deoxyxylulose 5-phosphate synthase required for chloroplast development to get photobleaching phenotype, thus can be used as a visual marker for VIGS efficiency (Mendel M.A., et al. 1996; Xiquan G. et al, 2011). Full-length Arabidopsis *RLP23* sequence was used as a query to blast them against the *Gossypium hirsutum* cDNA database to identify their cotton orthologs (Gh_A07G1586-Gh_D07G1774; GhRLP23_1, Gh_D07G1953; GhRLP23_2, Gh_A11G2283; GhRLP23_3A, Gh_D09G2477; GhRLP23_3D). Other candidates RLPs were chosen as ancestors based on clusters on GhRLPs phylogenetic tree. These ancestors corresponding homologs in Arabidopsis RLPs were used to rename cotton orthologs (Gh_D01G0395; AtRLP34, Gh_D11G2968; AtRLP27, Gh_D05G3192; AtRLP7, Gh_A03G0773; GSO1, Gh_D04G1293; AtRLP6, Gh_A12G0722; AtRLP44, and Gh_D13G2467; AtRLP9). The primers were designed to amplify conserved DNA fragments of the orthologs for inserting them into the VIGS vector (pTRV2). The mixed 1:1 ratio agrobacterium culture including both VIGS vectors, pTRV1 and pTRV2: Ghgene were inoculated into the emerging two cotyledons of cultivar FM9169B2F *Gossypium hirsutum* below 1 cm from the cotyledons with sterile insulin syringe. At least 15 plants were used for each construct. After GhCLA1 VIGSed plants showed photobleaching phenotype, a solution of 0.001% Tween containing 10^7 conidia/ml *F. oxysporum* spores was inoculated into the stems of cottons with sterile insulin syringe.

Infected plants were observed for 25 days post-inoculation to calculate disease index of population.

3.6.3 Phenotype Observation and Disease Severity

Unclear phenotype in a single mutant background of the AtRLP genes complicates to clarify their roles in biological process (Wang G., et al, 2008). Condition-specific manner or multiple functions for a gene may affect the obvious phenotype. Previous studies on AtRLP genes with specific elicitors suggested that gene expression levels, phenotype of a single mutant background and over expression of AtRLP genes can cause variations (Wu J., et al. 2016). We didn't observe any physiological phenotype after gene silencing of cotton seedlings. Fusarium inoculated plants were observed 25 days post inoculation with green fluorescent protein (GFP) and GhCLA1 as control groups to measure VIGS efficiency and disease severity (Appendix F) (Fig 13).

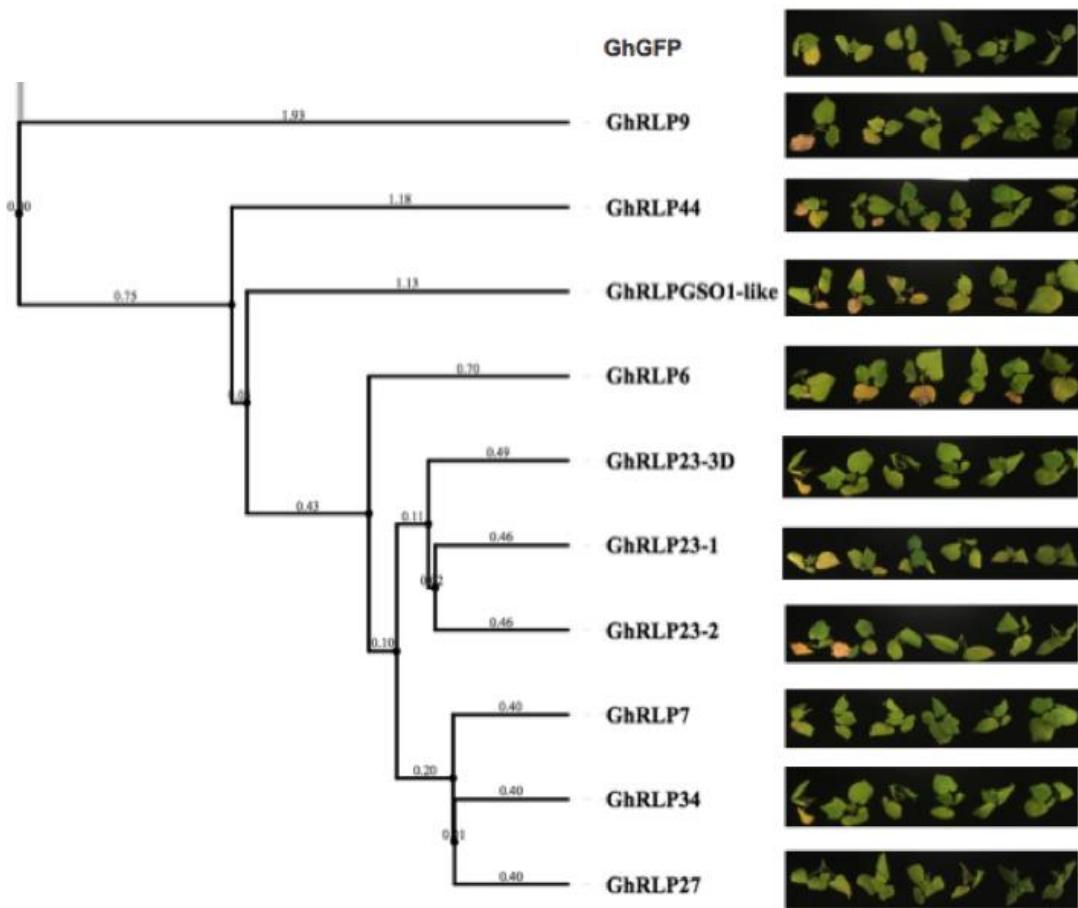

Figure 13. Phylogenetic tree and phenotypic observation of VIGSed plants

At least 15 plants were infected with *Fusarium oxysporum* below 1 cm cotyledons with sterile insulin syringe. VIGSed plants revealed three different phenotypes such as wilt, yellowish, and death cells. The disease symptom was divided into 4 levels (level 0-4) and calculated using the formula $DI = (\sum (n \times \text{number of seedlings at level } n)) / (4 \times \text{number of total seedlings} \times 100)$ (n refers the severity of the disease level of the plants). After the infected plant become obvious, disease index of

infected and VIGSed populations were scored based on true leaves phenotype containing cotyledons during 25 days post inoculation (Table 8).

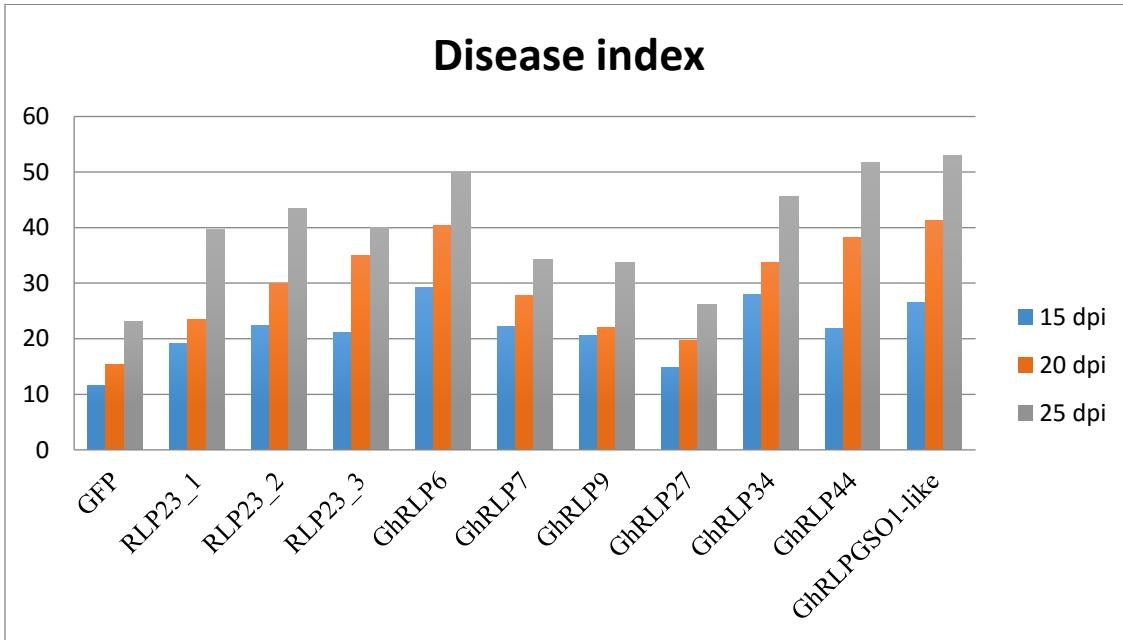

Table 8. Disease index of infected cottons

GhRLPGSO1-like, GhRLP44, GhRLP6, and GhRLP34 are more susceptible in comparison to GFP with 2.30, 2.24, 2.16, and 1.97 folds increase, respectively (Appendix F).

4. CONCLUSIONS

Cotton is a significant crop worldwide as with economic characteristics involving disease resistance, fiber production, and oil ingredient. The Arabidopsis genome has 56 of 57 e-LRR-RLPs and one malectin-like RLP. The protein sequences of AtRLPs were used as queries to blast against the *Gossypium* protein database at <https://www.cottongen.org/tools/blast/blast>. Blast analysis indicated that *G. arboreum*, *G. raimondii*, and *G. hirsutum* genome have 85, 105, and 145 eLRR-RLPs, respectively. The Arabidopsis genome has one malectin-like receptor-like protein, whereas *G. arboreum*, *G. raimondii*, and *G. hirsutum* have 1, 2 and 6, respectively (Table 2). LRR-RLPs appear to be evolved rapidly as the homology between cotton and Arabidopsis LRR-RLPs is often below 40%. The chromosomal location, full length, amino acid sequence and gene IDs were obtained at the *Gossypium* genome database in all cotton species. The protein mass and isoelectric point of the whole RLPs were calculated by using IPC server (Lukasz P. Kozlowski, 2016) (Table 3, Table 4, and Table 5). To classify the evolutionary relationships of the receptor like proteins in all species a phylogenetic analysis was conducted using UPGMA.

Well-studied RLP23 in Arabidopsis were used to identify its orthologs in *G. hirsutum* genome database and some ancestors on GhRLPs phylogenetic clusters were used to set up VIGS construct which were transferred to Agrobacterium. Agrobacterium cultures including pTVR1 and pTVR2: CLA1 or pTVR2: GFP, or pTVR2: Gene were infiltrated into stems of cotton seedlings below 1 cm cotyledons with sterile insulin syringe. After

photobleaching phenotype observed, *Fusarium oxysporum* (10^7 spors.ml¹) was inoculated into stems. GhRLPGSO1-like, GhRLP44, GhRLP6, and GhRLP34 silenced plants showed more susceptibility than others. These results suggest that receptor-like proteins in plants might be valuable candidate genes for further studies to investigate the disease resistance potential and breeding approaches.
