(57) **ABSTRACT**
An inbred *sorghum* line, designated R07007, is disclosed. The invention relates to the seeds of inbred *sorghum* line R07007, to the plants of inbred *sorghum* line R07007 and to methods for producing a *sorghum* plant by crossing the inbred line R07007 with itself or another *sorghum* line. The invention further relates to hybrid *sorghum* seeds and plants produced by crossing the inbred line R07007 with another *sorghum* line. The invention further relates to methods for producing a *sorghum* plant containing in its genetic material one or more transgenes and to the transgenic plants produced by that method and to methods for producing other inbred *sorghum* lines derived from the inbred R07007.

22 Claims, No Drawings

INBRED SORGHUM LINE 'R07007'

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a non-provisional application of and claims priority to U.S. Provisional Patent Application No. 61/260,197, filed on Nov. 11, 2009, which is herein incorporated by reference in its entirety.

BACKGROUND OF THE INVENTION

The present invention relates to a new and distinctive *sorghum* line, designated R07007. All publications cited in this application are herein incorporated by reference.

The new inbred *sorghum* line R07007 can be used as a parent in combination with one or more other parents to produce hybrid *sorghum*. Depending on the characteristics and combining ability of the parents, such *sorghum* hybrids may be grown for biomass, sugar, forage, and/or grain.

As a biomass crop, *sorghum* can be of any of the many varieties which have a high biomass. Many of these varieties are photoperiod sensitive and do not flower when grown in temperate latitudes. The continuous growth of vegetative biomass uninterrupted by flowering allows these varieties to produce significantly more vegetative biomass in comparison to grain sorghums. These high biomass *sorghum* varieties and hybrids also comprise genetic backgrounds that have been selected for based on increased plant height, increased biomass, increased growth rate, and lack of dwarfing genes, among other traits.

As a sugar crop, *sorghum* can be of any of the many varieties which have a high sugar content. Stalks are used for producing biofuel by squeezing the juice and then fermenting into a liquid biofuel, such as ethanol. Varieties of *sorghum* grown for sugar content can be open pollinated varieties or hybrids. In addition to squeezing stalks for juice, *sorghum* biomass may be treated with chemicals or industrial processes to release simple and complex sugars which can then be used in biofuel production. Varieties of *sorghum* grown for sugar content can be characterized by high brix values or by other more refined measurements of sugar components.

As a forage crop, the genus *Sorghum* includes three principal distinct morphotypes that are used as forages: forage sorghums, sudangrass, and *sorghum*×sudangrass hybrids. These three morphotypes have grossly different phenotypes and different modes of principal utilization. Forage sorghums have very coarse stems and wide leaves, similar to corn (*Zea mays* L.), very low tillering capacity, and very slow speed of regrowth after cutting. Consequently they are used nearly exclusively as a silage crop, never for hay production and only occasionally as direct pasture. Sudangrass in comparison is very grassy, characterized by very fine stems and narrow leaf blades, profuse tiller development, and exceptionally rapid recovery after cutting or grazing. Sudangrass (*Sorghum bicolor* ssp. *sudanense* L.) is an important forage species for pasture, grazing, green chop silage, hay and seed. Sudangrass is also referred to by the scientific name *sorghum*×*drummondii* (Steudel) Millsp. & Chase (= *S. bicolor*×*S. arundinaceum*) (R. F. Barnes and J. B. Beard (ed.), Glossary of Crop Science Terms, Crop Science Society of America, July 1992, pg. 84). Classification and species relationships of *sorghum* and sudangrass are discussed in several reports (Harlan and deWet, 1972; Celarier, 1958). For a comprehensive review of the floral characteristics, plant culture, and methods of self-pollinating or hybridizing sudangrass, see Shertz and Dalton, *Sorghum* 41:577-588, In Hybridization of Crop Plants, Fehr

et al. (ed.), American Society of Agronomy Inc. (1980). *Sorghum*×sudangrass hybrids (*Sorghum bicolor*×*S. bicolor* spp. *sudanense*) which result from crossing a *sorghum* female with a sudangrass male are generally intermediate in character expression between *sorghum* and sudangrass. *Sorghum*×sudangrass hybrids are also commonly referred to as *sorghum*-sudangrass hybrids, *sorghum*/sudangrass, sudax, and sudex, (Sudax® is a registered trademark). Adding somewhat to the confusion of the nomenclature, those skilled in the art sometimes refer to *sorghum*×sudangrass hybrids as "sudangrass hybrids". See, e.g., Miller and Stroup, 2003.

As a grain crop, *Sorghum bicolor* (L) Moench, is the fifth most important cereal after rice, wheat, maize, and barley. It constitutes the main food grain for over 750 million people who live in the semi-arid tropics of Africa, Asia, and Latin America. The largest group of producers are small-scale subsistence farmers with minimal access to production inputs such as fertiliser(s), pesticides, improved seeds (hybrids or varieties), good soil and water and improved credit facilities for their purchase.

There are many types of *sorghum* ranging in seed color from white through red to brown. Traditional types are open pollinated from which rural farmers retain seed for planting in the next season. Grain yields tend to be lower than the modern hybrids which are slowly being introduced. Commercial production of hybrid seed is a problem in many developing countries, and some rural farmers do not appreciate that harvested hybrid grain cannot be retained for planting the next season. Therefore they find *sorghum* production from hybrid seed expensive, even though the grain yields are higher than the land races. Resource-poor farmers prefer varieties incorporating the characteristics of resistance to insects, disease, drought, birds, and with acceptable yields of both grain for human consumption and fodder for livestock feed.

There are numerous steps in the development of any novel, desirable plant germplasm. Plant breeding begins with the analysis and definition of problems and weaknesses of the current germplasm, the establishment of program goals, and the definition of specific breeding objectives. The next step is selection of germplasm that possess the traits to meet the program goals. The goal is to combine in a single variety an improved combination of desirable traits from the parental germplasm. These important traits may include higher seed yield, higher biomass yield, higher sugar yield, improved composition traits, improved conversion traits, resistance to diseases and insects, better stems and roots, tolerance to low temperatures, and better agronomic characteristics on grain quality.

Choice of breeding or selection methods depends on the mode of plant reproduction, the heritability of the trait(s) being improved, and the type of cultivar used commercially (e.g., F₁ hybrid cultivar, pureline cultivar, etc.). For highly heritable traits, a choice of superior individual plants evaluated at a single location will be effective, whereas for traits with low heritability, selection should be based on mean values obtained from replicated evaluations of families of related plants. Popular selection methods commonly include pedigree selection, modified pedigree selection, mass selection, and recurrent selection, or a combination of these methods.

The complexity of inheritance influences choice of the breeding method. Backcross breeding is used to transfer one or a few favorable genes for a highly heritable trait into a desirable cultivar. This approach has been used extensively for breeding disease-resistant cultivars. Various recurrent selection techniques are used to improve quantitatively inherited traits controlled by numerous genes. The use of recurrent

selection in self-pollinating crops depends on the ease of pollination, the frequency of successful hybrids from each pollination, and the number of hybrid offspring from each successful cross.

Each breeding program should include a periodic, objective evaluation of the efficiency of the breeding procedure. Evaluation criteria vary depending on the goal and objectives, but should include gain from selection per year based on comparisons to an appropriate standard, overall value of the advanced breeding lines, and number of successful cultivars produced per unit of input (e.g., per year, per dollar expended, etc.).

Promising advanced breeding lines are thoroughly tested and compared to appropriate standards in environments representative of the commercial target area(s) for three or more years. The best lines are candidates for new commercial cultivars; those still deficient in a few traits may be used as parents to produce new populations for further selection. Inbred *sorghum* lines may be field tested in target area(s) for seed production for three or more years.

These processes, which lead to the final step of marketing and distribution of a *sorghum* hybrid, usually take from 8 to 12 years from the time the first cross is made and may rely on the development of improved breeding lines as precursors. Therefore, development of new cultivars is a time-consuming process that requires precise forward planning, efficient use of resources, and a minimum of changes in direction.

A most difficult task is the identification of individuals that are genetically superior, because for most traits the true genotypic value is masked by other confounding plant traits or environmental factors. One method of identifying a superior plant is to observe its performance relative to other experimental plants and to a widely grown standard cultivar. If a single observation is inconclusive, replicated observations provide a better estimate of its genetic worth.

The goal of *sorghum* plant breeding is to develop new, unique and superior *sorghum* lines and hybrids. The breeder initially selects and crosses two or more parental lines, followed by self-pollination and selection, producing many new genetic combinations. The breeder can theoretically generate billions of different genetic combinations via crossing, selfing, and mutations. The breeder has no direct control at the cellular level. Therefore, two breeders will never develop the same line, or even very similar lines, having the same *sorghum* traits.

Each year, the plant breeder selects the germplasm to advance to the next generation. This germplasm is grown under unique and different geographical, climatic and soil conditions, and further selections are then made, during and at the end of the growing season. The cultivars which are developed are unpredictable. This unpredictability is because the breeder's selection occurs in unique environments, with no control at the DNA level (using conventional breeding procedures), and with millions of different possible genetic combinations being generated. A breeder of ordinary skill in the art cannot predict the final resulting lines he develops, except possibly in a very gross and general fashion. The same breeder cannot produce the same line twice by using the exact same original parents and the same selection techniques. This unpredictability results in the expenditure of large amounts of research monies to develop superior new *sorghum* cultivars.

The development of new *sorghum* lines requires the development and selection of *sorghum* lines, the crossing of these lines and selection of superior hybrid crosses. The hybrid seed is produced by manual crosses between selected male-fertile parents or by using male sterility systems. Additional

data on parental lines, as well as the phenotype of the hybrid, influence the breeder's decision whether to continue with the specific hybrid cross.

Pedigree breeding and recurrent selection breeding methods are used to develop cultivars from breeding populations. Breeding programs combine desirable traits from two or more cultivars or various broad-based sources into breeding pools from which cultivars are developed by selfing and selection of desired phenotypes. The new cultivars are evaluated to determine which have commercial potential.

Pedigree breeding is used commonly for the improvement of self-pollinating crops. Two parents which possess favorable, complementary traits are crossed to produce an F_1 . An F_2 population is produced by selfing one or several F_1 's. Selection of the best individuals may begin in the F_2 population; then, beginning in the F_3 , the best individuals in the best families are selected. Replicated testing of families can begin in the F_4 generation to improve the effectiveness of selection for traits with low heritability. At an advanced stage of inbreeding (i.e., F_6 and F_7), the best lines or mixtures of phenotypically similar lines are tested for potential release as new cultivars.

Mass and recurrent selections can be used to improve populations of either self- or cross-pollinating crops. A genetically variable population of heterozygous individuals is either identified or created by intercrossing several different parents. The best plants are selected based on individual superiority, outstanding progeny, or excellent combining ability. The selected plants are intercrossed to produce a new population in which further cycles of selection are continued.

Backcross breeding has been used to transfer genes for a simply inherited, highly heritable trait into a desirable homozygous cultivar or inbred line which is the recurrent parent. The source of the trait to be transferred is called the donor parent. The resulting plant is expected to have the attributes of the recurrent parent (e.g., cultivar) and the desirable trait transferred from the donor parent. After the initial cross, individuals possessing the phenotype of the donor parent are selected and repeatedly crossed (backcrossed) to the recurrent parent. The resulting plant is expected to have the attributes of the recurrent parent (e.g., cultivar) and the desirable trait transferred from the donor parent.

The single-seed descent procedure in the strict sense refers to planting a segregating population, harvesting a sample of one seed per plant, and using the one seed sample to plant the next generation. When the population has been advanced from the F_2 to the desired level of inbreeding, the plants from which lines are derived will each trace to different F_2 individuals. The number of plants in a population declines each generation due to failure of some seeds to germinate or some plants to produce at least one seed. As a result, not all of the F_2 plants originally sampled in the population will be represented by a progeny when generation advance is completed.

Sorghum inbred lines are typically developed by first crossing two parent plants which may or may not be inbred. The parents may have traits which the breeder desires to combine. Typically, a few plants are chosen from the resulting segregating F_2 population, and these plants are self pollinated for several generations in combination with selecting for increased uniformity and/or increased homozygosity. The resulting new inbred lines can then be tested with other inbred lines to determine combining ability and suitability as parents for hybrids. Utilizing male sterile parental lines, *sorghum* hybrids may be made that have two (single hybrid) or three (double hybrid) parents.

Descriptions of other breeding methods that are commonly used for different traits and crops can be found in one of

several reference books (e.g., Allard, 1960; Simmonds, 1979; Sneep, et al., 1979; Fehr, 1987).

Proper testing should detect any major faults and establish the level of superiority or improvement over current lines and hybrids. In addition to showing superior performance, there must be a demand for a new line and hybrid that is compatible with industry standards or which creates a new market. The introduction of a new line or hybrid will incur additional costs to the seed producer, the grower, processor and consumer; for special advertising and marketing, altered seed and commercial production practices, and new product utilization. The testing preceding release of a new line or hybrid should take into consideration research and development costs as well as technical superiority of the final cultivar.

Sorghum, *Sorghum bicolor* (L.) Moench, is an important and valuable crop. Thus, a continuing goal of plant breeders is to develop stable, high yielding *sorghum* lines and hybrids that are agronomically sound. The reasons for this goal are obviously to maximize the amount of grain, biomass, sugar, biofuel/acre, and/or biopower/acre produced on the land used and to supply food and fuel for both animals and humans. To accomplish this goal, the *sorghum* breeder must select and develop *sorghum* plants that have the traits that result in superior lines and hybrids.

The foregoing examples of the related art and limitations related therewith are intended to be illustrative and not exclusive. Other limitations of the related art will become apparent to those of skill in the art upon a reading of the specification.

SUMMARY OF THE INVENTION

The following embodiments and aspects thereof are described in conjunction with systems, tools and methods which are meant to be exemplary and illustrative, not limiting in scope. In various embodiments, one or more of the above described problems have been reduced or eliminated, while other embodiments are directed to other improvements.

According to the invention, there is provided a novel *sorghum* line designated R07007. This invention thus relates to the seeds of *sorghum* line R07007, to the plants of *sorghum* line R07007, and to methods for producing a *sorghum* plant produced by crossing *sorghum* line R07007 with itself or another *sorghum* line.

Thus, any such methods using *sorghum* line R07007 are part of this invention: selfing, backcrosses, hybrid production, crosses to populations, and the like. All plants produced using *sorghum* line R07007 as a parent are within the scope of this invention. Advantageously, the *sorghum* line could be used in crosses with other, different, *sorghum* plants to produce first generation (F_1) *sorghum* hybrid seeds and plants with superior characteristics.

In another aspect, the present invention provides for single gene converted plants of *sorghum* line R07007. The single transferred gene may preferably be a dominant or recessive allele. Preferably, the single transferred gene will confer such traits as herbicide resistance, insect resistance, resistance for bacterial, fungal, or viral disease, male fertility, male sterility, enhanced nutritional quality, and industrial usage. The single gene may be a naturally occurring *sorghum* gene or a transgene introduced through genetic engineering techniques.

In another aspect, the present invention provides regenerable cells for use in tissue culture of *sorghum* plant R07007. The tissue culture will preferably be capable of regenerating plants having the physiological and morphological characteristics of the foregoing *sorghum* plant, and of regenerating plants having substantially the same genotype as the foregoing *sorghum* plant. Preferably, the regenerable cells in such

tissue cultures will be embryo, protoplast, meristematic cell, callus, pollen, glume, panicle leaf, pollen, ovule, cotyledon, hypocotyl, root, root tip, pistil, anther, floret, seed, stalk and rachis. Still further, the present invention provides *sorghum* plants regenerated from the tissue cultures of the invention.

Grain *sorghum* is an important and valuable food and feed grain crop. Thus, a continuing goal of plant breeders is to develop stable high yielding *sorghum* hybrids that are agronomically sound. The reasons for this goal are obvious to maximize the amount of grain produced on the land used and to supply food for both animals and humans.

In addition to the exemplary aspects and embodiments described above, further aspects and embodiments will become apparent by study of the following description's.

DEFINITIONS

In the description and tables which follow, a number of terms are used. In order to provide a clear and consistent understanding of the specification and claims, including the scope to be given such terms, the following definitions are provided:

Allele. Allele is any of one or more alternative forms of a gene, all of which relate to one trait or characteristic. In a diploid cell or organism, the two alleles of a given gene occupy corresponding loci on a pair of homologous chromosomes.

Backcrossing. Backcrossing is a process in which a breeder repeatedly crosses hybrid progeny back to one of the parents, for example, a first generation hybrid F_1 with one of the parental genotypes of the F_1 hybrid.

Essentially all the physiological and morphological characteristics. A plant having essentially all the physiological and morphological characteristics means a plant having the physiological and morphological characteristics of the cultivar, except for the characteristics derived from a converted gene.

Gene. As used herein, "gene" refers to a segment of nucleic acid. A gene can be introduced into a genome of a species, whether from a different species or from the same species, using transformation or various breeding methods.

Gene Converted (Conversion). Gene converted (conversion) plant refers to plants which are developed by backcrossing, genetic engineering or mutation wherein essentially all of the desired morphological and physiological characteristics of a variety are recovered in addition to the one or more traits transferred into the variety via the backcrossing technique, genetic engineering, or mutation.

Plant Height. Plant height in centimeters is taken from soil surface to the tip of the extended panicle at harvest.

Quantitative Trait Loci (QTL). Quantitative trait loci (QTL) refer to genetic loci that control to some degree numerically representable traits that are usually continuously distributed.

Regeneration. Regeneration refers to the development of a plant from tissue culture.

DETAILED DESCRIPTION OF THE INVENTION

Sorghum line R07007 is a re-selection made in 2002 from a segregating population from a variant of *sorghum* line EBA-3, a two-dwarf dual-purpose grain and forage *sorghum*. The segregated population was part of the Texas AgriLife Research *sorghum* breeding program. Upon growout of the population, a diverse range of maturities, including maturities with photoperiod sensitivity and insensitivity were discovered. Selection for various types of maturities was undertaken

and inbred lines were derived that were photoperiod insensitive. Testcross evaluation of photoperiod insensitive lines identified those that produced photoperiod insensitive hybrids with R07007 among these lines. Additional testing of R07007 revealed that it had high yield potential but had limited viability as a forage *sorghum*. Upon the development of the bioenergy breeding program, R07007 was once again brought forward for testing and evaluation. *Sorghum* line R07007 was observed for four years, from 2006 to 2009 during seed production and seed increase and was determined to be stable and uniform.

Inbred *sorghum* line R07007 has the following morphologic and other characteristics (based primarily on data collected at College Station, Tex.).

TABLE 1

VARIETY DESCRIPTION INFORMATION	
General Categories:	
Kind:	Sorghum
Inbred type:	Restorer
Use class:	High biomass
Maturity:	
Days from planting to mid-anthesis:	70
Number of days earlier than Tx623:	3
Plant:	
Coleoptile:	Green
Plant pigment:	Red
Stalk:	
Diameter:	Mid-stout
Height from soil to top of panicle:	175 cm
	Greater than Atlas by 60 cm
Waxy bloom:	Absent
Tillers:	Moderate
Sweetness:	Insipid
Juiciness:	Dry (pithy)
Panicle exertion:	Medium
Degree of senescence:	Intermediate
Leaf (first leaf below flag leaf):	
Width (relative to class):	Narrow
Color:	Light green
Margin:	Smooth
Attitude:	Drooping
Ligule:	Absent
Midrib color:	White
Panicle:	
Anther color (at flowering):	Light yellow
Length (cm):	15 cm
Density:	Semi-compact
Shape:	Obovate
Length of central rachis (% of panicle length):	100%
Rachis branches (at grain maturity):	Erect
Rachis branch average:	Short
Glumes:	
Length:	Intermediate
% of grain covered by glume:	75%
Texture:	Papery
Color:	Light tan
Hairiness:	Intermediate
Venation:	Absent
Transverse wrinkle:	Absent
Awns:	Intermediate
Roots:	Rhizomatous
Grain:	
Testa:	Absent
Mesocarp thickness:	Thick
Epicarp color (genetic):	Lemon yellow
Grain color (appearance):	Lemon yellow
Endosperm:	
Color:	White
Type:	Starchy
Texture:	Floury
Seed shape:	Ovate

This invention is also directed to methods for producing a *sorghum* plant by crossing a first parent *sorghum* plant with a second parent *sorghum* plant wherein either the first or second

parent *sorghum* plant is the *sorghum* plant of inbred *sorghum* line R07007. Further, both first and second parent *sorghum* plants can come from inbred *sorghum* line R07007. When self-pollinated, or crossed with another inbred *sorghum* plant, inbred *sorghum* line R07007 will be stable while when crossed with another, different *sorghum* line, an F₁ hybrid seed is produced.

An inbred line has been produced through several cycles of self-pollination and is therefore to be considered as a homozygous line. An inbred line can also be produced through the dihaploid system which involves doubling the chromosomes from a haploid plant thus resulting in an inbred line that is genetically stable (homozygous) and can be reproduced without altering the inbred line. A hybrid variety is classically created through the fertilization of an ovule from an inbred parental line by the pollen of another, different inbred parental line. Due to the homozygous state of the inbred line, the produced gametes carry a copy of each parental chromosome. As both the ovule and the pollen bring a copy of the arrangement and organization of the genes present in the parental lines, the genome of each parental line is present in the resulting F₁ hybrid, theoretically in the arrangement and organization created by the plant breeder in the original parental line.

As long as the homozygosity of the parental lines is maintained, the resulting hybrid cross is stable. The F₁ hybrid is then a combination of phenotypic characteristics issued from two arrangement and organization of genes, both created by a person skilled in the art through the breeding process.

Still further, this invention also is directed to methods for producing an inbred *sorghum* line R07007-derived *sorghum* plant by crossing inbred *sorghum* line R07007 with a second *sorghum* plant and growing the progeny seed, and repeating the crossing and growing steps with the inbred *sorghum* line R07007-derived plant from 0 to 7 times. Thus, any such methods using inbred *sorghum* line R07007 are part of this invention: selfing, backcrosses, hybrid production, crosses to populations, and the like. All plants produced using inbred *sorghum* line R07007 as a parent are within the scope of this invention, including plants derived from inbred *sorghum* line R07007. Advantageously, the inbred *sorghum* line is used in crosses with other, different, *sorghum* inbreds to produce first generation (F₁) *sorghum* hybrid seeds and plants with superior characteristics.

It should be understood that the inbred can, through routine manipulation of cytoplasmic or other factors, be produced in a male-sterile form. Such embodiments are also contemplated within the scope of the present claims. As used herein, the term plant includes plant cells, plant protoplasts, plant cell tissue cultures from which corn plants can be regenerated, embryo, protoplast, meristematic cell, callus, pollen, glume, panicle leaf, pollen, ovule, cotyledon, hypocotyl, root, root tip, pistil, anther, floret, seed, stalk and rachis and the like.

FURTHER EMBODIMENTS OF THE INVENTION

The advent of new molecular biological techniques has allowed the isolation and characterization of genetic elements with specific functions, such as encoding specific protein products. Scientists in the field of plant biology developed a strong interest in engineering the genome of plants to contain and express foreign genetic elements, or additional, or modified versions of native or endogenous genetic elements in order to alter the traits of a plant in a specific manner. Any DNA sequences, whether from a different species or from the same species, which are introduced into the genome using transformation or various breeding methods are referred to

herein collectively as “transgenes.” In some embodiments of the invention, a transgenic variant of inbred *sorghum* line R07007 may contain at least one transgene but could contain at least 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, and/or no more than 15, 14, 13, 12, 11, 10, 9, 8, 7, 6, 5, 4, 3, or 2. Over the last fifteen to twenty years several methods for producing transgenic plants have been developed, and the present invention also relates to transgenic variants of the claimed inbred *sorghum* line R07007.

Nucleic acids or polynucleotides refer to RNA or DNA that is linear or branched, single or double stranded, or a hybrid thereof. The term also encompasses RNA/DNA hybrids. These terms also encompass untranslated sequence located at both the 3' and 5' ends of the coding region of the gene: at least about 1000 nucleotides of sequence upstream from the 5' end of the coding region and at least about 200 nucleotides of sequence downstream from the 3' end of the coding region of the gene. Less common bases, such as inosine, 5-methylcytosine, 6-methyladenine, hypoxanthine and others can also be used for antisense, dsRNA and ribozyme pairing. For example, polynucleotides that contain C-5 propyne analogues of uridine and cytidine have been shown to bind RNA with high affinity and to be potent antisense inhibitors of gene expression. Other modifications, such as modification to the phosphodiester backbone, or the 2'-hydroxy in the ribose sugar group of the RNA can also be made. The antisense polynucleotides and ribozymes can consist entirely of ribonucleotides, or can contain mixed ribonucleotides and deoxyribonucleotides. The polynucleotides of the invention may be produced by any means, including genomic preparations, cDNA preparations, in vitro synthesis, RT-PCR, and in vitro or in vivo transcription.

One embodiment of the invention is a process for producing inbred *sorghum* line R07007 further comprising a desired trait, said process comprising introducing a transgene that confers a desired trait to a *sorghum* plant of inbred *sorghum* line R07007. Another embodiment is the product produced by this process. In one embodiment the desired trait may be one or more of herbicide resistance, insect resistance, disease resistance, decreased phytate, or modified fatty acid or carbohydrate metabolism. The specific gene may be any known in the art or listed herein, including: a polynucleotide conferring resistance to imidazolinone, dicamba, sulfonylurea, glyphosate, glufosinate, triazine, benzonitrile, cyclohexanedione, phenoxy propionic acid, and L-phosphinothricin; a polynucleotide encoding a *Bacillus thuringiensis* polypeptide; a polynucleotide encoding phytase, FAD-2, FAD-3, galactinol synthase, or a raffinose synthetic enzyme; or a polynucleotide conferring resistance to various diseases.

Numerous methods for plant transformation have been developed, including biological and physical plant transformation protocols. See, for example, Mild et al., “Procedures for Introducing Foreign DNA into Plants,” in *Methods in Plant Molecular Biology and Biotechnology*, Glick and Thompson Eds., CRC Press, Inc., Boca Raton, pp. 67-88 (1993), and Armstrong, “The First Decade of Maize Transformation: A Review and Future Perspective,” *Maydica*, 44:101-109 (1999). In addition, expression vectors and in vitro culture methods for plant cell or tissue transformation and regeneration of plants are available. See, for example, Gruber, et al., “Vectors for Plant Transformation,” in *Methods in Plant Molecular Biology and Biotechnology*, Glick and Thompson Eds., CRC Press, Inc., Boca Raton, pp. 89-119 (1993).

A genetic trait which has been engineered into the genome of a particular *sorghum* plant may then be moved into the genome of another variety using traditional breeding tech-

niques that are well known in the plant breeding arts. For example, a backcrossing approach is commonly used to move a transgene from a transformed *sorghum* variety into an already developed *sorghum* variety, and the resulting backcross conversion plant would then comprise the transgene(s).

Various genetic elements can be introduced into the plant genome using transformation. These elements include, but are not limited to, genes, coding sequences, inducible, constitutive and tissue specific promoters, enhancing sequences, and signal and targeting sequences. For example, see the traits, genes, and transformation methods listed in U.S. Pat. No. 6,118,055.

Plant transformation involves the construction of an expression vector which will function in plant cells. Such a vector comprises DNA comprising a gene under control of, or operatively linked to, a regulatory element (for example, a promoter). The expression vector may contain one or more such operably linked gene/regulatory element combinations. The vector(s) may be in the form of a plasmid and can be used alone or in combination with other plasmids to provide transformed *sorghum* plants using transformation methods as described below to incorporate transgenes into the genetic material of the *sorghum* plant(s).

Genetic Marker Profile of R07007

In addition to phenotypic observations, a plant can also be identified by its genotype. The genotype of a plant can be characterized through a genetic marker profile which can identify plants of the same variety or a related variety or be used to determine or validate a pedigree. Means of performing genetic marker profiles using genetic polymorphisms are well known in the art. For example, genetic marker profiles can be obtained by techniques such as Restriction Fragment Length Polymorphisms (RFLPs), Randomly Amplified Polymorphic DNAs (RAPDs), Arbitrarily Primed Polymerase Chain Reaction (AP-PCR), DNA Amplification Fingerprinting (DAF), Sequence Characterized Amplified Regions (SCARs), Amplified Fragment Length Polymorphisms (AFLPs), Simple Sequence Repeats (SSRs) which are also referred to as Microsatellites, and Single Nucleotide Polymorphisms (SNPs). For example, see Cregan et al., “An Integrated Genetic Linkage Map of the Soybean Genome” *Crop Sci* 39:1464-1490 (1999), and Berry et al., “Assessing Probability of Ancestry Using Simple Sequence Repeat Profiles: Applications to Maize Inbred Lines and Soybean Varieties” *Genetics* 165:331-342 (2003), each of which are incorporated by reference for this purpose.

Particular markers used for these purposes are not limited to any particular set of markers, but are envisioned to include any type of marker and marker profile which provides a means of distinguishing varieties. For example, genetic polymorphisms can be discrete allelic sequence differences in a population. Typically, an allele that is present at 1% or greater is considered to be a genetic polymorphism.

In addition to being used for identification of *sorghum* line R07007 and plant parts and plant cells of line R07007, the genetic profile may be used to identify a *sorghum* plant produced through the use of R07007 or to verify a pedigree for progeny plants produced through the use of R07007. The genetic marker profile is also useful in breeding and developing backcross conversions.

An R07007 *sorghum* plant can be characterized by molecular and physiological data obtained from the representative sample of said variety deposited with the American Type Culture Collection (ATCC). A *sorghum* plant formed by the combination of the disclosed R07007 *sorghum* plant or plant

cell with another *sorghum* plant or cell and comprising the alleles, combination of alleles, or allele frequencies of the variety.

In addition, plants and plant parts substantially benefiting from the use of R07007 in their development, such as R07007 comprising a backcross conversion, transgene, or genetic sterility factor, may be identified by having a molecular marker profile with a high percent identity to R07007. Such a percent identity might be 95%, 96%, 97%, 98%, 99%, 99.5% or 99.9% identical to R07007.

The genetic marker profile of R07007 also can be used to identify essentially derived varieties and other progeny varieties developed from the use of R07007, as well as cells and other plant parts thereof. Progeny plants and plant parts produced using R07007 may be identified by having a molecular marker profile of at least 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 76%, 77%, 78%, 79%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99% or 99.5% genetic contribution from *sorghum* variety R07007, as measured by either percent identity or percent similarity. Such progeny may be further characterized as being within a pedigree distance of R07007, such as within 1, 2, 3, 4 or 5 or less cross-pollinations to a *sorghum* plant other than R07007 or a plant that has R07007 as a progenitor. Unique molecular profiles may be identified with other molecular tools such as microsatellites or SNPs. Markers can be used to map QTLs that can also be used to distinguish R07007 or identify its potential progeny.

While determining the genetic marker profile of the plants described supra, a large number of SNIPs were examined and about 11 were identified which were unique to R07007. Such unique profiles may arise during the breeding process from recombination or mutation. A combination of several unique alleles provides a means of identifying a plant variety, an F₁ progeny produced from such variety, and progeny produced from such variety.

Expression Vectors for Transformation: Marker Genes

Expression vectors include at least one genetic marker, operably linked to a regulatory element (a promoter, for example) that allows transformed cells containing the marker to be either recovered by negative selection, i.e., inhibiting growth of cells that do not contain the selectable marker gene, or by positive selection, i.e., screening for the product encoded by the genetic marker. Many commonly used selectable marker genes for plant transformation are well known in the transformation arts, and include, for example, genes that code for enzymes that metabolically detoxify a selective chemical agent which may be an antibiotic or an herbicide, or genes that encode an altered target which is insensitive to the inhibitor. A few positive selection methods are also known in the art.

One commonly used selectable marker gene for plant transformation is the neomycin phosphotransferase II (nptII) gene, isolated from transposon Tn5, which when placed under the control of plant regulatory signals confers resistance to kanamycin. Fraley, et al., *Proc. Natl. Acad. Sci. U.S.A.*, 80:4803 (1983). Another commonly used selectable marker gene is the hygromycin phosphotransferase gene which confers resistance to the antibiotic hygromycin. Vanden Elzen, et al., *Plant Mol. Biol.*, 5:299 (1985).

Additional selectable marker genes of bacterial origin that confer resistance to antibiotics include gentamycin acetyl transferase, streptomycin phosphotransferase, and aminoglycoside-3'-adenyl transferase, the bleomycin resistance determinant. Hayford, et al., *Plant Physiol.*, 86:1216 (1988); Jones, et al., *Mol. Gen. Genet.*, 210:86 (1987); Svab, et al.,

Plant Mol. Biol., 14:197 (1990); Hille, et al., *Plant Mol. Biol.*, 7:171 (1986). Other selectable marker genes confer resistance to herbicides such as glyphosate, glufosinate, or bromoxynil. Comai, et al., *Nature*, 317:741-744 (1985); Gordon-Kamm, et al., *Plant Cell*, 2:603-618 (1990); and Stalker, et al., *Science*, 242:419-423 (1988).

Selectable marker genes for plant transformation not of bacterial origin include, for example, mouse dihydrofolate reductase, plant 5-enolpyruvylshikimate-3-phosphate synthase, and plant acetolactate synthase. Eichholtz, et al., *Somatic Cell Mol. Genet.*, 13:67 (1987); Shah, et al., *Science*, 233:478 (1986); Charest, et al., *Plant Cell Rep.*, 8:643 (1990).

Another class of marker genes for plant transformation requires screening of presumptively transformed plant cells rather than direct genetic selection of transformed cells for resistance to a toxic substance such as an antibiotic. These genes are particularly useful to quantify or visualize the spatial pattern of expression of a gene in specific tissues and are frequently referred to as reporter genes because they can be fused to a gene or gene regulatory sequence for the investigation of gene expression. Commonly used genes for screening presumptively transformed cells include β -glucuronidase (GUS), β -galactosidase, luciferase and chloramphenicol acetyltransferase. Jefferson, R. A., *Plant Mol. Biol. Rep.*, 5:387 (1987); Teeri, et al., *EMBO J.*, 8:343 (1989); Koncz, et al., *Proc. Natl. Acad. Sci. U.S.A.*, 84:131 (1987); DeBlock, et al., *EMBO J.*, 3:1681 (1984). Another approach to the identification of relatively rare transformation events has been use of a gene that encodes a dominant constitutive regulator of the *Zea mays* anthocyanin pigmentation pathway. Ludwig, et al., *Science*, 247:449 (1990).

In vivo methods for visualizing GUS activity that do not require destruction of plant tissue are available. Molecular Probes Publication 2908, IMAGENE GREEN, pp. 1-4 (1993) and Naleway, et al., *J. Cell Biol.*, 115:151a (1991). However, these in vivo methods for visualizing GUS activity have not proven useful for recovery of transformed cells because of low sensitivity, high fluorescent backgrounds and limitations associated with the use of luciferase genes as selectable markers.

More recently, a gene encoding Green Fluorescent Protein (GFP) has been utilized as a marker for gene expression in prokaryotic and eukaryotic cells. Chalfie, et al., *Science*, 263:802 (1994). GFP and mutants of GFP may be used as screenable markers.

Expression Vectors for Transformation: Promoters

Genes included in expression vectors must be driven by nucleotide sequence comprising a regulatory element, for example, a promoter. Several types of promoters are now well known in the transformation arts, as are other regulatory elements that can be used alone or in combination with promoters.

As used herein, "promoter" includes reference to a region of DNA upstream from the start of transcription and involved in recognition and binding of RNA polymerase and other proteins to initiate transcription. A "plant promoter" is a promoter capable of initiating transcription in plant cells. Examples of promoters under developmental control include promoters that preferentially initiate transcription in certain tissues, such as leaves, roots, seeds, fibers, xylem vessels, tracheids, or sclerenchyma. Such promoters are referred to as "tissue-preferred." Promoters which initiate transcription only in certain tissue are referred to as "tissue-specific." A "cell type" specific promoter primarily drives expression in certain cell types in one or more organs, for example, vascular cells in roots or leaves. An "inducible" promoter is a promoter which is under environmental control. Examples of environ-

mental conditions that may effect transcription by inducible promoters include anaerobic conditions or the presence of light. Tissue-specific, tissue-preferred, cell type specific, and inducible promoters constitute the class of "non-constitutive" promoters. A "constitutive" promoter is a promoter which is active under most environmental conditions.

The choice of promoter regions to be included in a recombinant construct depends upon several factors, including, but not limited to, efficiency, selectability, inducibility, desired expression level, and cell- or tissue-preferential expression. It is a routine matter for one of skill in the art to modulate the expression of a coding sequence by appropriately selecting and positioning promoter regions relative to the coding sequence. Transcription of a nucleic acid can be modulated in a similar manner.

Some suitable promoter regions initiate transcription only, or predominantly, in certain cell types. Methods for identifying and characterizing regulatory regions in plant genomic DNA are known, including, for example, those described in the following references: Jordano et al., *Plant Cell*, 1:855-866 (1989); Bustos et al., *Plant Cell*, 1:839-854 (1989); Green et al., *EMBO J.*, 7:4035-4044 (1988); Meier et al., *Plant Cell*, 3:309-316 (1991); and Zhang et al., *Plant Physiology*, 110:1069-1079 (1996).

Examples of various classes of promoter regions are described below. Some of the promoter regions indicated below as well as additional promoter regions are described in more detail in U.S. Patent Application Ser. Nos. 60/505,689; 60/518,075; 60/544,771; 60/558,869; 60/583,691; 60/619,181; 60/637,140; 60/757,544; 60/776,307; 10/957,569; 11/058,689; 11/172,703; 11/208,308; 11/274,890; 60/583,609; 60/612,891; 11/097,589; 11/233,726; 11/408,791; 11/414,142; 10/950,321; 11/360,017; PCT/US05/011105; PCT/US05/23639; PCT/US05/034308; PCT/US05/034343; PCT/US06/038236; PCT/US06/040572; and PCT/US07/62762.

For example, the sequences of promoter regions p326, YP0144, YP0190, p13879, YP0050, p32449, 21876, YP0158, YP0214, YP0380, PT0848, PT0633, YP0128, YP0275, PT0660, PT0683, PT0758, PT0613, PT0672, PT0688, PT0837, YP0092, PT0676, PT0708, YP0396, YP0007, YP0111, YP0103, YP0028, YP0121, YP0008, YP0039, YP0115, YP0119, YP0120, YP0374, YP0101, YP0102, YP0110, YP0117, YP0137, YP0285, YP0212, YP0097, YP0107, YP0088, YP0143, YP0156, PT0650, PT0695, PT0723, PT0838, PT0879, PT0740, PT0535, PT0668, PT0886, PT0585, YP0381, YP0337, PT0710, YP0356, YP0385, YP0384, YP0286, YP0377, PD1367, PT0863, PT0829, PT0665, PT0678, YP0086, YP0188, YP0263, PT0743 and YP0096 are set forth in international application no. PCT/US06/040572; the sequence of promoter region PT0625 is set forth in international application no. PCT/US05/034343; the sequences of promoter regions PT0623, YP0388, YP0087, YP0093, YP0108, YP0022 and YP0080 are set forth in U.S. Pat. No. 7,214,789; the sequence of promoter region PR0924 is set forth in international application no. PCT/US07/062762; and the sequences of promoter regions p530c10, pOsFIE2-2, pOsMEA, pOsYp102, and pOsYp285 are set forth in international application no. PCT/US06/038236.

It will be appreciated that a promoter region may meet criteria for one classification based on its activity in one plant species, and yet meet criteria for a different classification based on its activity in another plant species.

Broadly Expressing Promoters

A promoter can be said to be "broadly expressing" when it promotes transcription in many, but not necessarily all, plant

tissues. For example, a broadly expressing promoter can promote transcription of an operably linked sequence in one or more of the shoot, shoot tip (apex), and leaves, but weakly or not at all in tissues such as roots or stems. As another example, a broadly expressing promoter can promote transcription of an operably linked sequence in one or more of the stem, shoot, shoot tip (apex), and leaves, but can promote transcription weakly or not at all in tissues such as reproductive tissues of flowers and developing seeds. Non-limiting examples of broadly expressing promoters that can be included in the nucleic acid constructs provided herein include the p326, YP0144, YP0190, p13879, YP0050, p32449, 21876, YP0158, YP0214, YP0380, PT0848, and PT0633 promoters. Additional examples include the cauliflower mosaic virus (CaMV) 35S promoter, the mannopine synthase (MAS) promoter, the 1' or 2' prime promoters derived from T-DNA of *Agrobacterium tumefaciens*, the figwort mosaic virus 34S promoter, actin promoters such as the rice actin promoter, and ubiquitin promoters such as the maize ubiquitin-1 promoter. In some cases, the CaMV 35S promoter is excluded from the category of broadly expressing promoters.

Root Promoters

Root-active promoters confer transcription in root tissue, e.g., root endodermis, root epidermis, or root vascular tissues. In some embodiments, root-active promoters are root-preferential promoters, i.e., confer transcription only or predominantly in root tissue. Root-preferential promoters include the YP0128, YP0275, PT0625, PT0660, PT0683, and PT0758 promoters. Other root-preferential promoters include the PT0613, PT0672, PT0688, and PT0837 promoters, which drive transcription primarily in root tissue and to a lesser extent in ovules and/or seeds. Other examples of root-preferential promoters include the root-specific subdomains of the CaMV 35S promoter (Lam et al., *Proc. Natl. Acad. Sci. USA*, 86:7890-7894 (1989)), root cell specific promoters reported by Colliding et al., *Plant Physiol.*, 93:1203-1211 (1990), and the tobacco RD2 promoter.

Maturing Endosperm Promoters

In some embodiments, promoters that drive transcription in maturing endosperm can be useful. Transcription from a maturing endosperm promoter typically begins after fertilization and occurs primarily in endosperm tissue during seed development and is typically highest during the cellularization phase. Most suitable are promoters that are active predominantly in maturing endosperm, although promoters that are also active in other tissues can sometimes be used. Non-limiting examples of maturing endosperm promoters that can be included in the nucleic acid constructs provided herein include the napin promoter, the Arcelin-5 promoter, the phaseolin promoter (Bustos et al., *Plant Cell*, 1(9):839-853 (1989)), the soybean trypsin inhibitor promoter (Riggs et al., *Plant Cell*, 1(6):609-621 (1989)), the ACP promoter (Baerson et al., *Plant Mol. Biol.*, 22(2):255-267 (1993)), the stearyl-ACP desaturase promoter (Slocombe et al., *Plant Physiol.*, 104(4):167-176 (1994)), the soybean α' subunit of β -conglycinin promoter (Chen et al., *Proc. Natl. Acad. Sci. USA*, 83:8560-8564 (1986)), the oleosin promoter (Hong et al., *Plant Mol. Biol.*, 34(3):549-555 (1997)), and zein promoters, such as the 15 kD zein promoter, the 16 kD zein promoter, 19 kD zein promoter, 22 kD zein promoter and 27 kD zein promoter. Also suitable are the Osgt-1 promoter from the rice glutelin-1 gene (Zheng et al., *Mol. Cell. Biol.*, 13:5829-5842 (1993)), the beta-amylase promoter, and the barley hordein promoter. Other maturing endosperm promoters include the YP0092, PT0676, and PT0708 promoters.

Ovary Tissue Promoters

Promoters that are active in ovary tissues such as the ovule wall and mesocarp can also be useful, e.g., a polygalacturonidase promoter, the banana TRX promoter, the melon actin promoter, YP0396, and PT0623. Examples of promoters that are active primarily in ovules include YP0007, YP0111, YP0092, YP0103, YP0028, YP0121, YP0008, YP0039, YP0115, YP0119, YP0120, and YP0374.

Embryo Sac/Early Endosperm Promoters

To achieve expression in embryo sac/early endosperm, regulatory regions can be used that are active in polar nuclei and/or the central cell, or in precursors to polar nuclei, but not in egg cells or precursors to egg cells. Most suitable are promoters that drive expression only or predominantly in polar nuclei or precursors thereto and/or the central cell. A pattern of transcription that extends from polar nuclei into early endosperm development can also be found with embryo sac/early endosperm-preferential promoters, although transcription typically decreases significantly in later endosperm development during and after the cellularization phase. Expression in the zygote or developing embryo typically is not present with embryo sac/early endosperm promoters.

Promoters that may be suitable include those derived from the following genes: *Arabidopsis* viviparous-1 (see, GenBank No. U93215); *Arabidopsis* atmycl (see, Urao (1996) Plant Mol. Biol., 32:571-57; Conceicao (1994) Plant, 5:493-505); *Arabidopsis* FIE (GenBank No. AF129516); *Arabidopsis* MEA; *Arabidopsis* FIS2 (GenBank No. AF096096); and FIE 1.1 (U.S. Pat. No. 6,906,244). Other promoters that may be suitable include those derived from the following genes: maize MAC1 (see, Sheridan (1996) Genetics, 142:1009-1020); maize Cat3 (see, GenBank No. L05934; Abler (1993) Plant Mol. Biol., 22:10131-1038). Other promoters include the following *Arabidopsis* promoters: YP0039, YP0101, YP0102, YP0110, YP0117, YP0119, YP0137, DME, YP0285, and YP0212. Other promoters that may be useful include the following rice promoters: p530c10, pOsFIE2-2, pOsMEA, pOsYp102, and pOsYp285.

Embryo Promoters

Regulatory regions that preferentially drive transcription in zygotic cells following fertilization can provide embryo-preferential expression. Most suitable are promoters that preferentially drive transcription in early stage embryos prior to the heart stage, but expression in late stage and maturing embryos is also suitable. Embryo-preferential promoters include the barley lipid transfer protein (Ltp1) promoter (Plant Cell Rep (2001) 20:647-654), YP0097, YP0107, YP0088, YP0143, YP0156, PT0650, PT0695, PT0723, PT0838, PT0879, and PT0740.

Photosynthetic Tissue Promoters

Promoters active in photosynthetic tissue confer transcription in green tissues such as leaves and stems. Most suitable are promoters that drive expression only or predominantly in such tissues. Examples of such promoters include the ribulose-1,5-bisphosphate carboxylase (RbcS) promoters such as the RbcS promoter from eastern larch (*Larix laricina*), the pine cab6 promoter (Yamamoto et al., Plant Cell Physiol., 35:773-778 (1994)), the Cab-1 promoter from wheat (Fejes et al., Plant Mol. Biol., 15:921-932 (1990)), the CAB-1 promoter from spinach (Lubberstedt et al., Plant Physiol., 104:997-1006 (1994)), the cab1R promoter from rice (Luan et al., Plant Cell, 4:971-981 (1992)), the pyruvate orthophosphate dikinase (PPDK) promoter from corn (Matsuoka et al., Proc. Natl. Acad. Sci. USA, 90:9586-9590 (1993)), the tobacco Lhcb1*2 promoter (Cerdan et al., Plant Mol. Biol., 33:245-255 (1997)), the *Arabidopsis thaliana* SUC2 sucrose-H⁺ symporter promoter (Truernit et al., Planta, 196:564-570

(1995)), and thylakoid membrane protein promoters from spinach (psaD, psaF, psaE, PC, FNR, atpC, atpD, cab, rbcS). Other photosynthetic tissue promoters include PT0535, PT0668, PT0886, YP0144, YP0380 and PT0585.

5 Vascular Tissue Promoters

Examples of promoters that have high or preferential activity in vascular bundles include YP0087, YP0093, YP0108, YP0022, and YP0080. Other vascular tissue-preferential promoters include the glycine-rich cell wall protein GRP 1.8 promoter (Keller and Baumgartner, Plant Cell, 3(10):1051-1061 (1991)), the Commelina yellow mottle virus (CoYMV) promoter (Medberry et al., Plant Cell, 4(2):185-192 (1992)), and the rice tungro bacilliform virus (RTBV) promoter (Dai et al., Proc. Natl. Acad. Sci. USA, 101(2):687-692 (2004)).

15 Inducible Promoters

Inducible promoters confer transcription in response to external stimuli such as chemical agents or environmental stimuli. For example, inducible promoters can confer transcription in response to hormones such as gibberellic acid or ethylene, or in response to light or drought. Examples of drought-inducible promoters include YP0380, PT0848, YP0381, YP0337, PT0633, YP0374, PT0710, YP0356, YP0385, YP0396, YP0388, YP0384, PT0688, YP0286, YP0377, PD1367, and PD0901. Examples of nitrogen-inducible promoters include PT0863, PT0829, PT0665, and PT0886. Examples of shade-inducible promoters include PR0924 and PT0678. An example of a promoter induced by salt is rd29A (Kasuga et al. (1999) Nature Biotech 17: 287-291).

30 Basal Promoters

A basal promoter is the minimal sequence necessary for assembly of a transcription complex required for transcription initiation. Basal promoters frequently include a "TATA box" element that may be located between about 15 and about 35 nucleotides upstream from the site of transcription initiation. Basal promoters also may include a "CCAAT box" element (typically the sequence CCAAT) and/or a GGGCG sequence, which can be located between about 40 and about 200 nucleotides, typically about 60 to about 120 nucleotides, upstream from the transcription start site.

Stem Promoters

A stem promoter may be specific to one or more stem tissues or specific to stem and other plant parts. Stem promoters may have high or preferential activity in, for example, epidermis and cortex, vascular cambium, procambium, or xylem. Examples of stem promoters include YP0018 which is disclosed in U.S. Publication No. US2006/0015970 and CryIA(b) and CryIA(c) (Braga et al. 2003, Journal of New Seeds 5:209-221).

50 Other Promoters

Other classes of promoters include, but are not limited to, shoot-preferential, callus-preferential, trichome cell-preferential, guard cell-preferential such as PT0678, tuber-preferential, parenchyma cell-preferential, and senescence-preferential promoters. Promoters designated YP0086, YP0188, YP0263, PT0758, PT0743, PT0829, YP0119, and YP0096, as described in the above-referenced patent applications, may also be useful.

Other Regulatory Regions

60 A 5' prime untranslated region (UTR) can be included in nucleic acid constructs described herein. A 5' prime UTR is transcribed, but is not translated, and lies between the start site of the transcript and the translation initiation codon and may include the +1 nucleotide. A 3' prime UTR can be positioned between the translation termination codon and the end of the transcript. UTRs can have particular functions such as increasing mRNA stability or attenuating translation.

Examples of 3' prime UTRs include, but are not limited to, polyadenylation signals and transcription termination sequences, e.g., a nopaline synthase termination sequence. Signal Sequences for Targeting Proteins to Subcellular Compartments

Transport of protein produced by transgenes to a subcellular compartment such as the chloroplast, vacuole, peroxisome, glyoxysome, cell wall, or mitochondrion, or for secretion into the apoplast, is accomplished by means of operably linking the nucleotide sequence encoding a signal sequence to the 5' and/or 3' region of a gene encoding the protein of interest. Targeting sequences at the 5' and/or 3' end of the structural gene may determine, during protein synthesis and processing, where the encoded protein is ultimately compartmentalized.

The presence of a signal sequence directs a polypeptide to either an intracellular organelle or subcellular compartment or for secretion to the apoplast. Many signal sequences are known in the art. See, for example, Becker, et al., *Plant Mol. Biol.*, 20:49 (1992); Close, P. S., Master's Thesis, Iowa State University (1993); Knox, C., et al., *Plant Mol. Biol.*, 9:3-17 (1987); Lerner, et al., *Plant Physiol.*, 91:124-129 (1989); Fontes, et al., *Plant Cell*, 3:483-496 (1991); Matsuoka, et al., *Proc. Natl. Acad. Sci.*, 88:834 (1991); Gould, et al., *J. Cell. Biol.*, 108:1657 (1989); Creissen, et al., *Plant J.*, 2:129 (1991); Kalderon, et al., *Cell*, 39:499-509 (1984); Steifel, et al., *Plant Cell*, 2:785-793 (1990).

Foreign Protein Genes and Agronomic Genes

With transgenic plants according to the present invention, a foreign protein can be produced in commercial quantities. Thus, techniques for the selection and propagation of transformed plants, which are well understood in the art, yield a plurality of transgenic plants which are harvested in a conventional manner, and a foreign protein then can be extracted from a tissue of interest or from total biomass. Protein extraction from plant biomass can be accomplished by known methods which are discussed, for example, by Heney and Orr, *Anal. Biochem.*, 114:92-6 (1981).

According to a preferred embodiment, the transgenic plant provided for commercial production of foreign protein is *sorghum*. In another preferred embodiment, the biomass of interest is seed. For the relatively small number of transgenic plants that show higher levels of expression, a genetic map can be generated, primarily via conventional RFLP, PCR, and SSR analysis, which identifies the approximate chromosomal location of the integrated DNA molecule. For exemplary methodologies in this regard, see *Methods in Plant Molecular Biology and Biotechnology*, Glick and Thompson Eds., CRC Press, Inc., Boca Raton, pp. 269-284 (1993). Map information concerning chromosomal location is useful for proprietary protection of a subject transgenic plant. If unauthorized propagation is undertaken and crosses made with other germplasm, the map of the integration region can be compared to similar maps for suspect plants, to determine if the latter have a common parentage with the subject plant. Map comparisons would involve hybridizations, RFLP, PCR, SSR, and sequencing, all of which are conventional techniques.

Through the transformation of *sorghum*, the expression of genes can be altered to enhance disease resistance, insect resistance, herbicide resistance, agronomic quality and other traits. Transformation can also be used to insert DNA sequences which control or help control male-sterility. DNA sequences native to *sorghum* as well as non-native DNA sequences can be transformed into *sorghum* and used to alter levels of native or non-native proteins. Various promoters, targeting sequences, enhancing sequences, and other DNA sequences can be inserted into the genome for the purpose of

altering the expression of proteins. Reduction of the activity of specific genes (also known as gene silencing, or gene suppression) is desirable for several aspects of genetic engineering in plants.

5 Many techniques for gene silencing are well-known to one of skill in the art, including, but not limited to, knock-outs (such as by insertion of a transposable element such as mu (Vicki Chandler, *The Maize Handbook*, ch. 118, Springer-Verlag (1994)) or other genetic elements such as a FRT, Lox, or other site specific integration site, antisense technology (see, e.g., Sheehy, et al., *PNAS USA*, 85:8805-8809 (1988); and U.S. Pat. Nos. 5,107,065; 5,453,566; and 5,759,829); co-suppression (e.g., Taylor, *Plant Cell*, 9:1245 (1997); Jorgensen, *Trends Biotech.*, 8(12):340-344 (1990); Flavell, *PNAS USA*, 91:3490-3496 (1994); Finnegan, et al., *Bio/Technology*, 12: 883-888 (1994); and Neuhuber, et al., *Mol. Gen. Genet.*, 244:230-241 (1994)); RNA interference (Napoli, et al., *Plant Cell*, 2:279-289 (1990); U.S. Pat. No. 5,034,323; Sharp, *Genes Dev.*, 13:139-141 (1999); Zamore, et al., *Cell*, 101:25-33 (2000); and Montgomery, et al., *PNAS USA*, 95:15502-15507 (1998)); virus-induced gene silencing (Burton, et al., *Plant Cell*, 12:691-705 (2000); and Baulcombe, *Curr. Op. Plant Bio.*, 2:109-113 (1999)); target-RNA-specific ribozymes (Haseloff, et al., *Nature*, 334: 585-591 (1988)); hairpin structures (Smith, et al., *Nature*, 407:319-320 (2000); WO 99/53050; and WO 98/53083); MicroRNA (Aukerman & Sakai, *Plant Cell*, 15:2730-2741 (2003)); ribozymes (Steinbeck, et al., *EMBO J.*, 11:1525 (1992); and Perriman, et al., *Antisense Res. Dev.*, 3:253 (1993)); oligonucleotide mediated targeted modification (e.g., PCT Publication Nos. WO 03/076574 and WO 99/25853); Zn-finger targeted molecules (e.g., PCT Publication Nos. WO 01/52620; WO 03/048345; and WO 00/42219); and other methods or combinations of the above methods known to those of skill in the art.

Likewise, by means of the present invention, agronomic genes can be expressed in transformed plants. More particularly, plants can be genetically engineered to express various phenotypes of agronomic interest. Exemplary genes implicated in this regard include, but are not limited to, those categorized below:

1. Genes that Confer Resistance to Pests or Disease and that Encode:

45 A. Plant disease resistance genes. Plant defenses are often activated by specific interaction between the product of a disease resistance gene (R) in the plant and the product of a corresponding avirulence (Avr) gene in the pathogen. A plant cultivar can be transformed with cloned resistance gene to engineer plants that are resistant to specific pathogen strains. See, for example, Jones, et al., *Science*, 266:789 (1994) (cloning of the tomato Cf-9 gene for resistance to *Cladosporium fulvum*); Martin, et al., *Science*, 262:1432 (1993) (tomato Pto gene for resistance to *Pseudomonas syringae* pv. tomato encodes a protein kinase); Mindrinos, et al., *Cell*, 78:1089 (1994) (*Arabidopsis* RSP2 gene for resistance to *Pseudomonas syringae*); McDowell & Woffenden, *Trends Biotechnol.*, 21(4): 178-83 (2003); and Toyoda, et al., *Transgenic Res.*, 11 (6):567-82 (2002).

60 B. A *Bacillus thuringiensis* protein, a derivative thereof or a synthetic polypeptide modeled thereon. See, for example, Geiser, et al., *Gene*, 48:109 (1986), who disclose the cloning and nucleotide sequence of a Bt δ -endotoxin gene. Moreover, DNA molecules encoding δ -endotoxin genes can be purchased from American Type Culture Collection, Manassas, Va., for example, under ATCC Accession Nos. 40098, 67136, 31995, and 31998.

C. A lectin. See, for example, the disclosure by Van Damme, et al., *Plant Molec. Biol.*, 24:25 (1994), who disclose the nucleotide sequences of several *Clivia miniata* mannose-binding lectin genes.

D. A vitamin-binding protein such as avidin. See, PCT Appl. No. US 93/06487. The application teaches the use of avidin and avidin homologues as larvicides against insect pests.

E. An enzyme inhibitor, for example, a protease or proteinase inhibitor or an amylase inhibitor. See, for example, Abe, et al., *J. Biol. Chem.*, 262:16793 (1987) (nucleotide sequence of *sorghum* cysteine proteinase inhibitor); Huub, et al., *Plant Molec. Biol.*, 21:985 (1993) (nucleotide sequence of cDNA encoding tobacco proteinase inhibitor I); Sumitani, et al., *Biosci. Biotech. Biochem.*, 57:1243 (1993) (nucleotide sequence of *Streptomyces nitrosporeus* α -amylase inhibitor).

F. An insect-specific hormone or pheromone such as an ecdysteroid and juvenile hormone, a variant thereof, a mimetic based thereon, or an antagonist or agonist thereof. See, for example, the disclosure by Hammock, et al., *Nature*, 344:458 (1990), of baculovirus expression of cloned juvenile hormone esterase, an inactivator of juvenile hormone.

G. An insect-specific peptide or neuropeptide which, upon expression, disrupts the physiology of the affected pest. For example, see the disclosures of Regan, *J. Biol. Chem.*, 269:9 (1994) (expression cloning yields DNA coding for insect diuretic hormone receptor), and Pratt, et al., *Biochem. Biophys. Res. Comm.*, 163:1243 (1989) (an allostatin is identified in *Diptera punctata*). See also, U.S. Pat. No. 5,266,317 to Tomalski, et al., who disclose genes encoding insect-specific, paralytic neurotoxins.

H. An insect-specific venom produced in nature by a snake, a wasp, etc. For example, see Pang, et al., *Gene*, 116:165 (1992), for disclosure of heterologous expression in plants of a gene coding for a scorpion insectotoxic peptide.

I. An enzyme responsible for a hyper-accumulation of a monoterpene, a sesquiterpene, a steroid, a hydroxamic acid, a phenylpropanoid derivative or another non-protein molecule with insecticidal activity.

J. An enzyme involved in the modification, including the post-translational modification, of a biologically active molecule; for example, a glycolytic enzyme, a proteolytic enzyme, a lipolytic enzyme, a nuclease, a cyclase, a transaminase, an esterase, a hydrolase, a phosphatase, a kinase, a phosphorylase, a polymerase, an elastase, a chitinase, and a glucanase, whether natural or synthetic. See, PCT Publication No. WO 93/02197 in the name of Scott, et al., which discloses the nucleotide sequence of a callase gene. DNA molecules which contain chitinase-encoding sequences can be obtained, for example, from the ATCC under Accession Nos. 39637 and 67152. See also, Kramer, et al., *Insect Biochem. Molec. Biol.*, 23:691 (1993), who teach the nucleotide sequence of a cDNA encoding tobacco hornworm chitinase, and Kawalleck, et al., *Plant Molec. Biol.*, 21:673 (1993), who provide the nucleotide sequence of the parsley ubi4-2 polyubiquitin gene.

K. A molecule that stimulates signal transduction. For example, see the disclosure by Botella, et al., *Plant Molec. Biol.*, 24:757 (1994), of nucleotide sequences for mung bean calmodulin cDNA clones, and Griess, et al., *Plant Physiol.*, 104:1467 (1994), who provide the nucleotide sequence of a maize calmodulin cDNA clone.

L. A hydrophobic moment peptide. See, PCT Publication No. WO 95/16776 (disclosure of peptide derivatives of Tachyplesin which inhibit fungal plant pathogens) and PCT Publication No. WO 95/18855 (teaches synthetic antimicrobial

peptides that confer disease resistance), the respective contents of which are hereby incorporated by reference.

M. A membrane permease, a channel former or a channel blocker. For example, see the disclosure of Jaynes, et al., *Plant Sci.*, 89:43 (1993), of heterologous expression of a cecropin- β , lytic peptide analog to render transgenic tobacco plants resistant to *Pseudomonas solanacearum*.

N. A viral-invasive protein or a complex toxin derived therefrom. For example, the accumulation of viral coat proteins in transformed plant cells imparts resistance to viral infection and/or disease development effected by the virus from which the coat protein gene is derived, as well as by related viruses. See, Beachy, et al., *Ann. Rev. Phytopathol.*, 28:451 (1990). Coat protein-mediated resistance has been conferred upon transformed plants against alfalfa mosaic virus, cucumber mosaic virus, tobacco streak virus, potato virus X, potato virus Y, tobacco etch virus, tobacco rattle virus, and tobacco mosaic virus. Id.

O. An insect-specific antibody or an immunotoxin derived therefrom. Thus, an antibody targeted to a critical metabolic function in the insect gut would inactivate an affected enzyme, killing the insect. Cf. Taylor, et al., Abstract #497, Seventh International Symposium on Molecular Plant-Microbe Interactions (Edinburgh, Scotland (1994)) (enzymatic inactivation in transgenic tobacco via production of single-chain antibody fragments).

P. A virus-specific antibody. See, for example, Tavladoraki, et al., *Nature*, 366:469 (1993), who show that transgenic plants expressing recombinant antibody genes are protected from virus attack.

Q. A developmental-arrestive protein produced in nature by a pathogen or a parasite. Thus, fungal endo- α -1,4-D-polygalacturonases facilitate fungal colonization and plant nutrient release by solubilizing plant cell wall homo- α -1,4-D-galacturonase. See, Lamb, et al., *Bio/Technology*, 10:1436 (1992). The cloning and characterization of a gene which encodes a bean endopolygalacturonase-inhibiting protein is described by Toubart, et al., *Plant J.*, 2:367 (1992).

R. A developmental-arrestive protein produced in nature by a plant. For example, Logemann, et al., *Bio/Technology*, 10:305 (1992), have shown that transgenic plants expressing the barley ribosome-inactivating gene have an increased resistance to fungal disease.

S. Genes involved in the Systemic Acquired Resistance (SAR) Response and/or the pathogenesis-related genes. Briggs, S., *Current Biology*, 5(2) (1995); Pieterse & Van Loon, *Curr. Opin. Plant Bio.*, 7(4):456-64 (2004) and Somsich, *Cell*, 113(7):815-6 (2003).

T. Antifungal genes. See, Cornelissen and Melchers, *Plant Physiol.*, 101:709-712 (1993); Parijs, et al., *Planta*, 183:258-264 (1991) and Bushnell, et al., *Can. J. of Plant Path.*, 20(2): 137-149 (1998). See also, U.S. Pat. No. 6,875,907.

U. Detoxification genes, such as for fumonisin, beauvericin, moniliformin, and zearalenone, and their structurally related derivatives. For example, see U.S. Pat. No. 5,792,931.

V. Cystatin and cysteine proteinase inhibitors. See U.S. Pat. No. 7,205,453.

W. Defensin genes. See PCT Publication No. WO 03/000863 and U.S. Pat. No. 6,911,577.

2. Genes that Confer Resistance to an Herbicide, for Example:

A. An herbicide that inhibits the growing point or meristem, such as an imidazolinone or a sulfonylurea. Exemplary genes in this category code for mutant ALS and AHAS enzyme as described, for example, by Lee, et al., *EMBO J.*, 7:1241 (1988) and Miki, et al., *Theor. Appl. Genet.*, 80:449 (1990), respectively.

B. Glyphosate (resistance conferred by mutant 5-enolpyruvylshikimate-3-phosphate synthase (EPSP) and *aroA* genes, respectively) and other phosphono compounds such as glufosinate (phosphinothricin acetyl transferase (PAT) and *Streptomyces hygrosopicus* PAT, bar, genes), and pyridinoxo or phenoxy propionic acids and cyclohexones (ACCase inhibitor-encoding genes). See, for example, U.S. Pat. No. 4,940,835 to Shah, et al., which discloses the nucleotide sequence of a form of EPSP which can confer glyphosate resistance. A DNA molecule encoding a mutant *aroA* gene can be obtained under ATCC Accession No. 39256, and the nucleotide sequence of the mutant gene is disclosed in U.S. Pat. No. 4,769,061 to Comai. European Pat. Appl. No. 0 333 033 to Kumada, et al. and U.S. Pat. No. 4,975,374 to Goodman, et al., disclose nucleotide sequences of glutamine synthetase genes which confer resistance to herbicides such as L-phosphinothricin. The nucleotide sequence of a PAT gene is provided in European Pat. Appl. No. 0 242 246 to Leemans, et al. DeGreef, et al., *Bio/Technology*, 7:61 (1989), describe the production of transgenic plants that express chimeric bar genes coding for PAT activity. Exemplary of genes conferring resistance to phenoxy propionic acids and cyclohexones, such as sethoxydim and haloxyfop are the *Acc1-S1*, *Acc1-S2*, and *Acc1-S3* genes described by Marshall, et al., *Theor. Appl. Genet.*, 83:435 (1992).

C. An herbicide that inhibits photosynthesis, such as a triazine (*psbA* and *gs+* genes) or a benzonitrile (nitrilase gene). Przibilla, et al., *Plant Cell*, 3:169 (1991), describe the transformation of *Chlamydomonas* with plasmids encoding mutant *psbA* genes. Nucleotide sequences for nitrilase genes are disclosed in U.S. Pat. No. 4,810,648 to Stalker, and DNA molecules containing these genes are available under ATCC Accession Nos. 53435, 67441, and 67442. Cloning and expression of DNA coding for a glutathione S-transferase is described by Hayes, et al., *Biochem. J.*, 285:173 (1992).

3. Genes that Confer or Contribute to a Value-Added Trait, Such as:

A. Modified lignin content, for example, by introducing or transforming a plant with genes that alter lignin content. See, Li, X., et al., *Plant J.* (2008) 54(4): 569-581 and Saballos, A., et al., *Genetics* (2009) 181(2): 783-795.

B. Modified plant height, for example, by introducing or transforming a plant with genes that alter plant height (*Dw3* and *dw3*). See, Brown, P. J., et al., *Genetics*. (2008) 180(1) 629-637.

C. Modified profused wax and cuticular features, for example, by introducing or transforming plants with genes that alter the cuticle/wax pathway for improvement of abiotic stress tolerance. See, Burrow, G. B., et al., *Theor. Appl. Genet.* (2009) 118(3): 423-431 and McIntyre, C. L., et al., *Genome* (2008) 51(7): 524-533.

D. Modified diurnal oscillation, for example, by introducing or transforming a plant with an antisense gene of starch branching enzyme (SBE). See, Mutisya, J., et al., *J. Plant Physiol.* (2009) 166(4): 428-434.

E. Modified fatty acid metabolism, for example, by transforming a plant with an antisense gene of stearyl-ACP desaturase to increase stearic acid content of the plant. See, Knultzon, et al., *Proc. Natl. Acad. Sci. U.S.A.*, 89:2624 (1992).

F. Decreased phytate content. 1) Introduction of a phytase-encoding gene would enhance breakdown of phytate, adding more free phosphate to the transformed plant. For example, see, Van Hartingsveldt, et al., *Gene*, 127:87 (1993), for a disclosure of the nucleotide sequence of an *Aspergillus niger* phytase gene; 2) A gene could be introduced that reduced phytate content. In maize, this, for example, could be accomplished by cloning and then reintroducing DNA associated

with the single allele which is responsible for maize mutants characterized by low levels of phytic acid. See, Raboy, et al., *Maydica*, 35:383 (1990).

G. Modified cell wall composition effected, for example, by transforming plants with a gene coding for an enzyme that alters the cell wall components, such as but not limited to lignin, cellulose, xylan, hemicellulose, and saccharides. See, WO2008/069878 and US 2009-0070899 A1, for examples of genes that can be used to alter cell wall composition.

4. Male Sterility:

Genes that Control Male Sterility

There are several methods of conferring genetic male sterility available, such as multiple mutant genes at separate locations within the genome that confer male sterility, as disclosed in U.S. Pat. Nos. 4,654,465 and 4,727,219 to Brar, et al., and chromosomal translocations as described by Patterson in U.S. Pat. Nos. 3,861,709 and 3,710,511. In addition to these methods, Albertsen, et al., U.S. Pat. No. 5,432,068, describes a system of nuclear male sterility which includes: identifying a gene which is critical to male fertility; silencing this native gene which is critical to male fertility; removing the native promoter from the essential male fertility gene and replacing it with an inducible promoter; inserting this genetically engineered gene back into the plant; and thus creating a plant that is male sterile because the inducible promoter is not "on" resulting in the male fertility gene not being transcribed. Fertility is restored by inducing, or turning "on," the promoter, which in turn allows the gene that confers male fertility to be transcribed.

A. A dominant nuclear gene, *Ms(tc)* controlling male sterility. See, Elkonin, L. A., *Theor. Appl. Genet.* (2005) 111(7): 1377-1384.

B. A tapetum-specific gene, *RTS*, a *sorghum* anther-specific gene is required for male fertility and its promoter sequence directs tissue-specific gene expression in different plant species. Luo, Hong, et al., *Plant Molecular Biology*, 62(3): 397-408(12) (2006). Introduction of a deacetylase gene under the control of a tapetum-specific promoter and with the application of the chemical N—Ac—PPT. See International Publication No. WO 01/29237.

C. Introduction of various stamen-specific promoters. Anther-specific promoters which are of particular utility in the production of transgenic male-sterile monocots and plants for restoring their fertility. See, U.S. Pat. No. 5,639,948. See also, International Publication Nos. WO 92/13956 and WO 92/13957.

D. Introduction of the barnase and the barstar genes. See, Paul, et al., *Plant Mol. Biol.*, 19:611-622 (1992).

Alteration of Male Sterility Systems

For additional examples of nuclear male and female sterility systems and genes, see also, U.S. Pat. Nos. 5,859,341, 6,297,426, 5,478,369, 5,824,524, 5,850,014, and 6,265,640. See also, Hanson, Maureen R., et al., "Interactions of Mitochondrial and Nuclear Genes That Affect Male Gametophyte Development," *Plant Cell*, 16:S154-S169 (2004), all of which are hereby incorporated by reference.

A. Modification of RNA editing within mitochondrial open reading frames. See, Pring, D. R., et al, *Curr. Genet.* (1998) 33(6): 429-436; Pring, D. R., et al., *J. Hered.* (1999) 90(3): 386-393; Pring, D. R., et al., *Curr. Genet.* (2001) 39(5-6): 371-376; and Hedgcoth, C., et al., *Curr. Genet.* (2002) 41(5): 357-365.

B. Cytoplasmic male sterility (CMS) from mutations at *atp6* codons. See, Kempken, F., *FEBS. Lett.* (1998): 441(2): 159-160.

C. Inducing male sterility through heat shock. See, Wang, L., *Yi Chuan Xue Bao.* (2000) 27(9): 834-838.

D. Inducing male sterility through treatment of streptomycin on *sorghum* callus cultures. See, Elkonin, L. A., et al., *Genetica* (2008) 44(5): 663-673.

5. Genes that Create a Site for Site Specific DNA Integration:

This includes the introduction of FRT sites that may be used in the FLP/FRT system and/or Lox sites that may be used in the Cre/Loxp system. For example, see, Lyznik, et al., Site-Specific Recombination for Genetic Engineering in Plants, *Plant Cell Rep.*, 21:925-932 (2003) and International Publication No. WO 99/25821, which are hereby incorporated by reference. Other systems that may be used include the Gin recombinase of phage Mu (Maeser, et al. (1991); Vicki Chandler, *The Maize Handbook*, ch. 118, Springer-Verlag (1994), the Pin recombinase of *E. coli* (Enomoto, et al. (1983)), and the R/RS system of the pSR1 plasmid (Araki, et al. (1992)).

6. Genes that Affect Abiotic Stress Resistance:

Genes that affect abiotic stress resistance (including, but not limited to, flowering, panicle/glume and seed development, enhancement of nitrogen utilization efficiency, altered nitrogen responsiveness, drought resistance or tolerance, cold resistance or tolerance, and salt resistance or tolerance) and increased yield under stress.

A. Modified drought stress tolerance, for example, by introducing or transforming a plant with genes conferring drought stress tolerance. See, Srinivas, G., et al., *Theor. Appl. Genet.* (2009) February; 118(4): 703-717.

B. Modified salt tolerance, for example, by introducing or transforming plants with genes that confer tolerance to salt. See, Li, Y., *Pak. J. Biol. Sci.* (2008) May; 11(9): 1268-1272.

C. Modified cold tolerance, for example by introducing or transforming plants with genes that confer cold tolerance. See, Knoll, J., et al., *Theor. Appl. Genet.* (2008) 116(4): 577-587 and Knoll, J., et al., *Theor. Appl. Genet.* (2008) 116(4): 541-543.

For example, see: International Publication No. WO 00/73475 where water use efficiency is altered through alteration of malate; U.S. Pat. Nos. 5,892,009, 5,965,705, 5,929,305, 5,891,859, 6,417,428, 6,664,446, 6,717,034, and 6,801,104, and International Publication Nos. WO 2000/060089, WO 2001/026459, WO 2001/035725, WO 2001/034726, WO 2001/035727, WO 2001/036444, WO 2001/036597, WO 2001/036598, WO 2002/015675, WO 2002/017430, WO 2002/077185, WO 2002/079403, WO 2003/013227, WO 2003/013228, WO 2003/014327, WO 2004/031349, WO 2004/076638, WO 98/09521, and WO 99/38977 describing genes, including CBF genes and transcription factors effective in mitigating the negative effects of freezing, high salinity, and drought on plants, as well as conferring other positive effects on plant phenotype; U.S. Publication No. 2004/0148654 and International Publication No. WO 01/36596 where abscisic acid is altered in plants resulting in improved plant phenotype such as increased yield and/or increased tolerance to abiotic stress; International Publication Nos. WO 2000/006341 and WO 04/090143, U.S. Publication No. 2004/0237147, and U.S. Pat. No. 6,992,237, where cytokinin expression is modified resulting in plants with increased stress tolerance, such as drought tolerance and/or increased yield. Also see, International Publication Nos. WO 02/02776, WO 2003/052063, WO 01/64898, JP 2002281975, and U.S. Pat. Nos. 6,084,153, 6,177,275, and 6,107,547 (enhancement of nitrogen utilization and altered nitrogen responsiveness). For ethylene alteration, see, U.S. Publication Nos. 2004/0128719 and 2003/0166197 and International Publication No. WO 2000/32761. For plant transcription factors or transcriptional regulators of abiotic stress, see, e.g., U.S. Publication Nos. 2004/0098764 and 2004/0078852.

Other genes and transcription factors that affect plant growth and agronomic traits such as yield, flowering, plant growth, and/or plant structure, can be introduced or introgressed into plants, see, e.g., International Publication Nos. WO 97/49811 (LHY), WO 98/56918 (ESD4), WO 97/10339, WO 96/14414 (CON), WO 96/38560, WO 01/21822 (VRN1), WO 00/44918 (VRN2), WO 99/49064 (GI), WO 00/46358 (FR1), WO 97/29123, WO 99/09174 (D8 and Rht), and U.S. Pat. Nos. 6,573,430 (TFL), 6,713,663 (FT), 6,794,560, 6,307,126 (GAL), and International Publication Nos. WO 2004/076638 and WO 2004/031349 (transcription factors).

Examples of exogenous nucleic acid sequences that can be used in the methods described herein include, but are not limited to, sequences encoding genes or fragments thereof that modulate cold tolerance, frost tolerance, heat tolerance, drought tolerance, water use efficiency, nitrogen use efficiency, pest resistance, herbicide resistance, biomass, chemical composition, plant architecture, biopower conversion properties, and/or biofuel conversion properties. In particular, exemplary sequences are described in the following applications which are incorporated herein by reference in their entirety: U.S. Publication Nos. US20080131581, US20080072340, US20070277269, US20070214517, US20070192907, US 20070174936, US 20070101460, US 20070094750, US20070083953, US 20070061914, US20070039067, US20070006346, US20070006345, US20060294622, US20060195943, US20060168696, US20060150285, US20060143729, US20060134786, US20060112454, US20060057724, US20060010518, US20050229270, US20050223434, and US20030217388.

Methods for *Sorghum* Transformation

Numerous methods for plant transformation have been developed, including biological and physical plant transformation protocols. See, for example, Miki, et al., "Procedures for Introducing Foreign DNA into Plants," in *Methods in Plant Molecular Biology and Biotechnology*, Glick and Thompson Eds., CRC Press, Inc., Boca Raton, pp. 67-88 (1993). In addition, expression vectors and in vitro culture methods for plant cell or tissue transformation and regeneration of plants are available. See, for example, Gruber, et al., "Vectors for Plant Transformation," in *Methods in Plant Molecular Biology and Biotechnology*, Glick and Thompson Eds., CRC Press, Inc., Boca Raton, pp. 89-119 (1993).

A. *Agrobacterium*-mediated Transformation—One method for introducing an expression vector into plants is based on the natural transformation system of *Agrobacterium*. See, for example, Horsch, et al., *Science*, 227:1229 (1985). *A. tumefaciens* and *A. rhizogenes* are plant pathogenic soil bacteria which genetically transform plant cells. The Ti and Ri plasmids of *A. tumefaciens* and *A. rhizogenes*, respectively, carry genes responsible for genetic transformation of the plant. See, for example, Kado, C. I., *Crit. Rev. Plant Sci.*, 10:1 (1991). Descriptions of *Agrobacterium* vector systems and methods for *Agrobacterium*-mediated gene transfer are provided by Gruber, et al., supra, Miki, et al., supra; Moloney, et al., *Plant Cell Reports*, 8:238 (1989); *Agrobacterium*-mediated transformation of *sorghum* is provided by Zhao, Z. Y., et al., *Plant Mol. Biol.* (2000) 44(6): 789-798 and Gurel, et al., *Plant Cell Rep.* (2009) 28(3): 429-424. See also, U.S. Pat. No. 5,591,616, issued Jan. 7, 1997.

B. Direct Gene Transfer—Despite the fact the host range for *Agrobacterium*-mediated transformation is broad, some major cereal crop species and gymnosperms have generally been recalcitrant to this mode of gene transfer, even though some success has recently been achieved in *sorghum* and corn. Hiei, et al., *The Plant Journal*, 6:271-282 (1994) and

U.S. Pat. No. 5,591,616, issued Jan. 7, 1997. Several methods of plant transformation, collectively referred to as direct gene transfer, have been developed as an alternative to *Agrobacterium*-mediated transformation.

A generally applicable method of plant transformation is microprojectile-mediated transformation wherein DNA is carried on the surface of microprojectiles measuring 1 to 4 μm . The expression vector is introduced into plant tissues with a biolistic device that accelerates the microprojectiles to speeds of 300 to 600 m/s which is sufficient to penetrate plant cell walls and membranes. See, Casas, M., et al., *Proc. Natl. Acad. Sci. U.S.A.* (1993) 90(23): 11212-11216, for transformation of *sorghum* plants via microprojectile bombardment; Sanford, et al., *Part. Sci. Technol.*, 5:27 (1987); Sanford, J. C., *Trends Biotech.*, 6:299 (1988); Klein, et al., *Bio/Technology*, 6:559-563 (1988); Sanford, J. C., *Physiol Plant*, 7:206 (1990); Klein, et al., *Biotechnology*, 10:268 (1992). In corn, several target tissues can be bombarded with DNA-coated microprojectiles in order to produce transgenic plants, including, for example, callus (Type I or Type II), immature embryos, and meristematic tissue.

Another method for physical delivery of DNA to plants is sonication of target cells. Zhang, et al., *Bio/Technology*, 9:996 (1991). Additionally, liposome and spheroplast fusion have been used to introduce expression vectors into plants. Deshayes, et al., *EMBO J.*, 4:2731 (1985); Christou, et al., *Proc Natl. Acad. Sci. USA.*, 84:3962 (1987). Direct uptake of DNA into protoplasts using CaCl_2 precipitation, polyvinyl alcohol or poly-L-ornithine has also been reported. Hain, et al., *Mol. Gen. Genet.*, 199:161 (1985) and Draper, et al., *Plant Cell Physiol.*, 23:451 (1982). Electroporation of protoplasts and whole cells and tissues have also been described. Donn, et al., In Abstracts of VIIth International Congress on Plant Cell and Tissue Culture IAPTC, A2-38, p. 53 (1990); D'Halluin, et al., *Plant Cell*, 4:1495-1505 (1992); and Spencer, et al., *Plant Mol. Biol.*, 24:51-61 (1994).

Following transformation of *sorghum* target tissues, expression of the above-described selectable marker genes allows for preferential selection of transformed cells, tissues, and/or plants using regeneration and selection methods now well known in the art.

Genetic Marker Profile Through SSR and First Generation Progeny

In addition to phenotypic observations, a plant can also be identified by its genotype. The genotype of a plant can be characterized through a genetic marker profile which can identify plants of the same variety or a related variety or be used to determine or validate a pedigree. Genetic marker profiles can be obtained by techniques such as Isozyme Electrophoresis, Restriction Fragment Length Polymorphisms (RFLPs), Randomly Amplified Polymorphic DNAs (RAPDs), Arbitrarily Primed Polymerase Chain Reaction (AP-PCR), DNA Amplification Fingerprinting (DAF), Sequence Characterized Amplified Regions (SCARs), Amplified Fragment Length Polymorphisms (AFLPs), Simple Sequence Repeats (SSRs), which are also referred to as Microsatellites, and Single Nucleotide Polymorphisms (SNPs). For example, see, Yonemaru, J., et al., "Development of genome-wide simple sequence repeat markers using whole-genome shotgun sequences of *sorghum* (*Sorghum bicolor* (L.) Moench)," *DNA Res.* (2009) 16(3): 187-193; Duan Y., et al., "Construction of methylation linkage map based on MSAP and SSR markers in *Sorghum bicolor* (L.). IUMBMB Life (2009) 61(6): 663-669; Srinivas, G. et al., "Identification of quantitative trait loci for agronomically important traits and their association with genic-microsatellite markers in *sorghum*," *Theor. App. Genet.* (2009) 118(8):

1439-1454; Mace, E. S., et al., "A consensus genetic map of *sorghum* that integrates multiple component maps and high-throughput Diversity Array Technology (DArT) markers," *BMC Plant Biol.* (2009) 9:13; Cregan et al., "An Integrated Genetic Linkage Map of the Soybean Genome," *Crop Science*, 39:1464-1490 (1999), and Berry, et al., "Assessing Probability of Ancestry Using Simple Sequence Repeat Profiles: Applications to Maize Inbred Lines and Soybean Varieties," *Genetics*, 165:331-342 (2003), each of which are incorporated by reference herein in their entirety.

Particular markers used for these purposes are not limited to any particular set of markers, but are envisioned to include any type of marker and marker profile which provides a means of distinguishing varieties. One method of comparison is to use only homozygous loci for inbred *sorghum* line R07007.

Primers and PCR protocols for assaying these and other markers are widely known in the art. In addition to being used for identification of inbred *sorghum* line R07007 and plant parts and plant cells of *sorghum* line R07007, the genetic profile may be used to identify a *sorghum* plant produced through the use of *sorghum* line R07007 or to verify a pedigree for progeny plants produced through the use of *sorghum* line R07007. The genetic marker profile is also useful in breeding and developing backcross conversions.

The present invention comprises a *sorghum* line and hybrid plant characterized by molecular and physiological data obtained from the representative sample of said inbred line and or hybrid deposited with the American Type Culture Collection (ATCC). Further provided by the invention is a *sorghum* hybrid plant formed by the combination of the disclosed *sorghum* hybrid plant or plant cell with another *sorghum* plant or cell.

Means of performing genetic marker profiles using SSR polymorphisms are well-known in the art. SSRs are genetic markers based on polymorphisms in repeated nucleotide sequences, such as microsatellites. A marker system based on SSRs can be highly informative in linkage analysis relative to other marker systems in that multiple alleles may be present. Another advantage of this type of marker is that, through use of flanking primers, detection of SSRs can be achieved, for example, by the polymerase chain reaction (PCR), thereby eliminating the need for labor-intensive Southern hybridization. The PCR detection is done by use of two oligonucleotide primers flanking the polymorphic segment of repetitive DNA. Repeated cycles of heat denaturation of the DNA followed by annealing of the primers to their complementary sequences at low temperatures, and extension of the annealed primers with DNA polymerase, comprise the major part of the methodology.

Following amplification, markers can be scored by electrophoresis of the amplification products. Scoring of marker genotype is based on the size of the amplified fragment, which may be measured by the number of base pairs of the fragment. While variation in the primer used or in laboratory procedures can affect the reported fragment size, relative values should remain constant regardless of the specific primer or laboratory used. When comparing hybrids or varieties it is preferable if all SSR profiles are performed in the same lab.

Primers used may be publicly available and may be found in for example in U.S. Pat. Nos. 7,232,940, 7,217,003, 7,250,556, 7,214,851, 7,195,887, and 7,192,774.

In addition, plants and plant parts substantially benefiting from the use of *sorghum* line R07007 in their development, such as *sorghum* line R07007 comprising a backcross conversion, transgene, or genetic sterility factor, may be identi-

fied by having a molecular marker profile with a high percent identity to *sorghum* line R07007. Such a percent identity might be 95%, 96%, 97%, 98%, 99%, 99.5%, or 99.9% identical to *sorghum* line R07007.

The SSR profile of *sorghum* line R07007 also can be used to identify essentially derived varieties and other progeny varieties developed from the use of *sorghum* line R07007, as well as cells and other plant parts thereof. Such plants may be developed using the markers identified in International Publication No. WO 00/31964, U.S. Pat. No. 6,162,967, and U.S. application Ser. No. 09/954,773. Progeny plants and plant parts produced using *sorghum* line R07007 may be identified by having a molecular marker profile of at least 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 76%, 77%, 78%, 79%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99%, or 99.5% genetic contribution from a *sorghum* hybrid or line, as measured by either percent identity or percent similarity. Such progeny may be further characterized as being within a pedigree distance of *sorghum* line R07007, such as within 1, 2, 3, 4, or 5 or fewer cross-pollinations to a *sorghum* plant other than *sorghum* line R07007 or a plant that has *sorghum* line R07007 as a progenitor. Unique molecular profiles may be identified with other molecular tools such as SNPs and RFLPs.

While determining the SSR genetic marker profile of the plants described supra, several unique SSR profiles may also be identified which did not appear in either parent of such *sorghum* plant. Such unique SSR profiles may arise during the breeding process from recombination or mutation. A combination of several unique alleles provides a means of identifying a plant variety, an F₁ progeny produced from such inbred line, and progeny produced from such *sorghum* plant.

Gene Conversion

When the term "*sorghum* plant" is used in the context of the present invention, this also includes any gene conversions of that line. The term gene converted plant as used herein refers to those *sorghum* plants which are developed by a plant breeding technique called backcrossing wherein essentially all of the desired morphological and physiological characteristics of a cultivar are recovered in addition to the one or more genes transferred into the cultivar via the backcrossing technique. Backcrossing methods can be used with the present invention to improve or introduce a characteristic into the line. The term backcrossing as used herein refers to the repeated crossing of a hybrid progeny back to one of the parental *sorghum* plants, the recurrent parent, for that cultivar, i.e., backcrossing 1, 2, 3, 4, 5, 6, 7, 8, 9, or more times to the recurrent parent. The parental *sorghum* plant which contributes the gene for the desired characteristic is termed the nonrecurrent or donor parent. This terminology refers to the fact that the nonrecurrent parent is used one time in the backcross protocol and therefore does not recur. The parental *sorghum* plant to which the gene or genes from the nonrecurrent parent are transferred is known as the recurrent parent as it is used for several rounds in the backcrossing protocol (Poehlman & Sleper (1994); Fehr (1987)). In a typical backcross protocol, the original cultivar of interest (recurrent parent) is crossed to a second cultivar (nonrecurrent parent) that carries the single gene or genes of interest to be transferred. The resulting progeny from this cross are then crossed again to the recurrent parent and the process is repeated until a *sorghum* plant is obtained wherein essentially all of the desired morphological and physiological characteristics of the recurrent parent are recovered in the converted plant, in addition to one or more

transferred genes from the nonrecurrent parent as determined at the 5% significance level when grown in the same environmental conditions.

The selection of a suitable recurrent parent is an important step for a successful backcrossing procedure. The goal of a backcross protocol is to alter or substitute one or more traits or characteristics in the original cultivar. To accomplish this, one or more genes of the recurrent cultivar is modified or substituted with the desired gene or genes from the nonrecurrent parent, while retaining essentially all of the rest of the desired genetic, and therefore the desired physiological and morphological, constitution of the original cultivar. The choice of the particular nonrecurrent parent will depend on the purpose of the backcross; one of the major purposes is to add some commercially desirable, agronomically important trait to the plant. The exact backcrossing protocol will depend on the characteristic or trait being altered to determine an appropriate testing protocol. Although backcrossing methods are simplified when the characteristic(s) being transferred is a dominant allele, a recessive allele may also be transferred. In this instance it may be necessary to introduce a test of the progeny to determine if the desired characteristic has been successfully transferred.

Many single gene traits have been identified that are not regularly selected for in the development of a new cultivar but that can be improved by backcrossing techniques. Single gene traits may or may not be transgenic. Examples of these traits include, but are not limited to, male sterility, waxy starch, herbicide resistance, resistance for bacterial, fungal, or viral disease, insect resistance, male fertility, enhanced nutritional quality, industrial usage, yield stability, and yield enhancement. These genes are generally inherited through the nucleus. Some known exceptions to this are the genes for male sterility, some of which are inherited cytoplasmically, but still act as single gene traits. Several of these single gene traits are described in U.S. Pat. Nos. 5,777,196, 5,948,957, and 5,969,212, the disclosures of which are specifically hereby incorporated by reference.

Introduction of a New Trait or Locus into *Sorghum* Line R07007

Sorghum line R07007 represents a new base into which a new locus or trait may be introgressed. Direct transformation and backcrossing represent two important methods that can be used to accomplish such an introgression. The term backcross conversion and single locus conversion are used interchangeably to designate the product of a backcrossing program.

Backcross Conversions of *Sorghum* Line R07007

A backcross conversion of *sorghum* line R07007 occurs when DNA sequences are introduced through backcrossing (Hallauer, et al., "Corn Breeding," *Corn and Corn Improvements*, No. 18, pp. 463-481 (1988)), with *sorghum* line R07007 utilized as the recurrent parent. Both naturally occurring and transgenic DNA sequences may be introduced through backcrossing techniques. A backcross conversion may produce a plant with a trait or locus conversion in at least two or more backcrosses, including at least 2 crosses, at least 3 crosses, at least 4 crosses, at least 5 crosses, and the like. Molecular marker assisted breeding or selection may be utilized to reduce the number of backcrosses necessary to achieve the backcross conversion. For example, see, Openshaw, S. J., et al., Marker-assisted Selection in Backcross Breeding, in: *Proceedings Symposium of the Analysis of Molecular Data*, *Crop Science Society of America*, Corvallis, Ore. (August 1994), where it is demonstrated that a backcross conversion can be made in as few as two backcrosses.

The complexity of the backcross conversion method depends on the type of trait being transferred (single genes or closely linked genes as vs. unlinked genes), the level of expression of the trait, the type of inheritance (cytoplasmic or nuclear) and the types of parents included in the cross. It is understood by those of ordinary skill in the art that for single gene traits that are relatively easy to classify, the backcross method is effective and relatively easy to manage. (See, Hal-lauer, et al., in *Corn and Corn Improvement*, Sprague and Dudley, Third Ed. (1998)). Desired traits that may be trans-ferred through backcross conversion include, but are not lim-ited to, sterility (nuclear and cytoplasmic), fertility restora-tion, nutritional enhancements, drought tolerance, nitrogen utilization, altered fatty acid profile, low phytate, industrial enhancements, disease resistance (bacterial, fungal or viral), insect resistance, and herbicide resistance. In addition, an introgression site itself, such as an FRT site, Lox site, or other site specific integration site, may be inserted by backcrossing and utilized for direct insertion of one or more genes of interest into a specific plant variety. In some embodiments of the invention, the number of loci that may be backcrossed into *sorghum* line R07007 is at least 1, 2, 3, 4, or 5, and/or no more than 6, 5, 4, 3, or 2. A single locus may contain several transgenes, such as a transgene for disease resistance that, in the same expression vector, also contains a transgene for herbicide resistance. The gene for herbicide resistance may be used as a selectable marker and/or as a phenotypic trait. A single locus conversion of a site specific integration system allows for the integration of multiple genes at the converted loci.

Tissue Culture

Further reproduction of the variety can occur by tissue culture and regeneration. Tissue culture of various tissues of *sorghum* and regeneration of plants therefrom is well known and widely published. For example, reference may be had to Komatsuda, T., et al., *Crop Sci.*, 31:333-337 (1991); Stephens, P. A., et al., *Theor. Appl. Genet.*, 82:633-635 (1991); Komatsuda, T., et al., *Plant Cell, Tissue and Organ Culture*, 28:103-113 (1992); Dhir, S., et al., *Plant Cell Reports*, 11:285-289 (1992); Pandey, P., et al., *Japan J. Breed.*, 42:1-5 (1992); and Shetty, K., et al., *Plant Science*, 81:245-251 (1992); as well as U.S. Pat. No. 5,024,944, issued Jun. 18, 1991 to Collins, et al., and U.S. Pat. No. 5,008,200, issued Apr. 16, 1991 to Ranch, et al. Thus, another aspect of this invention is to provide cells which upon growth and differentiation produce *sorghum* plants having the physi-ological and morphological characteristics of *sorghum* line R07007.

As used herein, the term "tissue culture" indicates a com-position comprising isolated cells of the same or a different type or a collection of such cells organized into parts of a plant. Exemplary types of tissue cultures are embryo, proto-plast, meristematic cell, callus, pollen, glume, panicle leaf, pollen, ovule, cotyledon, hypocotyl, root, root tip, pistil, anther, floret, seed, stalk and rachis, and the like. Means for preparing and maintaining plant tissue culture are well known in the art. By way of example, a tissue culture comprising organs has been used to produce regenerated plants. U.S. Pat. Nos. 5,959,185; 5,973,234, and 5,977,445 describe certain techniques, the disclosures of which are incorporated herein by reference.

As used herein, the term "plant" includes plant cells, plant protoplasts, plant cells of tissue culture from which *sorghum* plants can be regenerated, plant calli, plant clumps, and plant cells that are intact in plants or parts of plants, such as embryo, protoplast, meristematic cell, callus, pollen, glume, panicle leaf, pollen, ovule, cotyledon, hypocotyl, root, root tip, pistil,

anther, floret, seed, stalk and rachis, and the like. Thus, another aspect of this invention is to provide for cells which upon growth and differentiation produce a cultivar having essentially all of the physiological and morphological char-acteristics of R07007.

The present invention contemplates a *sorghum* plant regen-erated from a tissue culture of a line (e.g., R07007) or hybrid plant of the present invention. As is well known in the art, tissue culture of *sorghum* can be used for the in vitro regen-eration of a *sorghum* plant. Tissue culture of various tissues of *sorghum* and regeneration of plants therefrom is well-known and widely published. For example, reference may be had to Chu, Q. R., et al., "A novel basal medium for embryogenic callus induction of Southern US crosses," *Rice Biotechnology Quarterly*, 32:19-20 (1997); and Oono, K., "Broadening the Genetic Variability By Tissue Culture Methods," *Jap. J. Breed.*, 33 (Suppl. 2), 306-307, illus. 1983. Thus, another aspect of this invention is to provide cells which upon growth and differentiation produce *sorghum* plants having the physi-ological and morphological characteristics of line R07007.

Duncan, et al., *Planta*, 165:322-332 (1985), reflects that 97% of the plants cultured that produced callus were capable of plant regeneration. Subsequent experiments with both cul-tivars and hybrids produced 91% regenerable callus that pro-duced plants. In a further study in 1988, Songstad, et al., *Plant Cell Reports*, 7:262-265 (1988), reports several media addi-tions that enhance regenerability of callus of two cultivars. Other published reports also indicated that "non-traditional" tissues are capable of producing somatic embryogenesis and plant regeneration. K. P. Rao, et al., *Maize Genetics Coop-eration Newsletter*, 60:64-65 (1986), refers to somatic embryogenesis from glume callus cultures and B. V. Conger, et al., *Plant Cell Reports*, 6:345-347 (1987), indicates somatic embryogenesis from the tissue cultures of corn leaf segments. Thus, it is clear from the literature that the state of the art is such that these methods of obtaining plants are routinely used and have a very high rate of success.

Tissue culture of corn, for example, is described in Euro-pean Patent Application Publication 160,390. Corn tissue culture procedures are also described in Green and Rhodes, "Plant Regeneration in Tissue Culture of Maize," *Maize for Biological Research*, Plant Molecular Biology Association, Charlottesville, Va., 367-372 (1982), and in Duncan, et al., "The Production of Callus Capable of Plant Regeneration from Immature Embryos of Numerous *Zea Mays* Geno-types," 165 *Planta*, 322:332 (1985). Thus, another aspect of this invention is to provide cells which upon growth and differentiation produce corn plants having the physiological and morphological characteristics of *sorghum* line R07007.

Crossing Methods and Hybrid Production

One or more of the methods of breeding described herein can be used with the *sorghum* inbred variety described herein. In some embodiments, the *sorghum* inbred variety described herein can be used in breeding as a parent to produce a *sorghum* hybrid. In some embodiments, the *sorghum* hybrid produced is a high biomass *sorghum*. In some embodiments, the *sorghum* inbred variety described herein can be used in breeding to develop a new inbred line through further selec-tion exclusively among plants of the inbred variety or by crossing the inbred variety with another variety and making further selections through selfed or backcrossed generations. Techniques such as haploid doubling and marker assisted selection for homozygosity can be used to accelerate the process of inbreeding.

Sorghum plants are bred in most cases by self pollination techniques. With the incorporation of male sterility (either genetic or cytoplasmic) cross pollination breeding techniques

can also be utilized. *Sorghum* has a perfect flower with both male and female parts in the same flower located in the panicle. The flowers are usually in pairs on the panicle branches. Natural pollination occurs in *sorghum* when anthers (male flowers) open and pollen falls onto receptive stigma (female flowers). Because of the close proximity of male (anthers) and female (stigma) in the panicle, self-pollination can be high. Cross-pollination may occur when wind or convection currents move pollen from the anthers of one plant to receptive stigma on another plant. Cross-pollination is greatly enhanced with incorporation of male sterility which renders male flowers nonviable without affecting the female flowers. Successful pollination in the case of male sterile flowers requires cross-pollination.

The development of *sorghum* hybrids requires the development of homozygous inbred lines, the crossing of these lines, and the evaluation of the crosses. Pedigree breeding methods, and to a lesser extent population breeding methods, are used to develop inbred lines from breeding populations. Breeding programs combine desirable traits from two or more inbred lines into breeding pools from which new inbred lines are developed by selfing and selection of desired phenotypes. The new inbreds are crossed with other inbred lines and the hybrids from these crosses are evaluated to determine which have commercial potential.

Pedigree breeding starts with the crossing of two genotypes, each of which may have one or more desirable characteristics that is lacking in the other or which complement the other. If the two original parents do not provide all of the desired characteristics, other sources can be included in the breeding population. In the pedigree method, superior plants are selfed and selected in successive generations. In the succeeding generations the heterozygous condition gives way to homogeneous lines as a result of self-pollination and selection. Typically, in the pedigree method of breeding five or more generations of selfing and selection is practiced. F_1 to F_2 ; F_2 to F_3 ; F_3 to F_4 ; F_4 to F_5 , etc.

Backcrossing can be used to improve an inbred line. Backcrossing transfers a specific desirable trait from one inbred or source to an inbred that lacks that trait. This can be accomplished for example by first crossing a superior inbred (A) (recurrent parent) to a donor inbred (non-recurrent parent), which carries the appropriate gene(s) for the trait in question. The progeny of this cross is then mated back to the superior recurrent parent (A) followed by selection in the resultant progeny for the desired trait to be transferred from the non-recurrent parent. After five or more backcross generations with selection for the desired trait, the progeny will be heterozygous for loci controlling the characteristic being transferred, but will be like the superior parent for most or almost all other genes. The last backcross generation would be selfed to give pure breeding progeny for the gene(s) being transferred.

A hybrid *sorghum* variety can be the cross of two inbred lines, each of which may have one or more desirable characteristics lacked by the other or which complement the other. The hybrid progeny of the first generation is designated F_1 . In the development of hybrids only the F_1 hybrid plants are sought. The hybrid is more vigorous than its inbred parents. This hybrid vigor, or heterosis, can be manifested in many ways, including increased vegetative growth and increased yield.

The development of a hybrid *sorghum* variety involves five steps: (1) the formation of "restorer" and "on-restorer" germplasm pools; (2) the selection of superior plants from various "restorer" and "non-restorer" germplasm pools; (3) the selling of the superior plants for several generations to pro-

duce a series of inbred lines, which although different from each other, each breed true and are highly uniform; (4) the conversion of inbred lines classified as non-restorers to cytoplasmic male sterile (CMS) forms, and (5) crossing the selected cytoplasmic male sterile (CMS) inbred lines with selected fertile inbred lines (restorer lines) to produce the hybrid progeny (F_1).

Because *sorghum* is normally a self-pollinated plant and because both male and female flowers are in the same panicle, large numbers of hybrid seed can only be produced by using cytoplasmic male sterile (CMS) inbreds. Inbred male sterile lines are developed by converting inbred lines to CMS. This is achieved by transferring the chromosomes of the line to be sterilized into sterile cytoplasm by a series of backcrosses, using a male sterile line as a female parent and the line to be sterilized as the recurrent and pollen parent in all crosses. After conversion to male sterility the line is designated the (A) line. Lines with fertility restoring genes cannot be converted into male sterile A-lines. The original line is designated the (B) line.

Flowers of the CMS inbred are fertilized with pollen from a male fertile inbred carrying genes which restore male fertility in the hybrid (F_1) plants. An important consequence of the homozygosity and homogeneity of the inbred lines is that the hybrid between any two inbreds will always be the same. Once the inbreds that give the best hybrid have been identified, the hybrid seed can be reproduced indefinitely as long as the homogeneity of the inbred parent is maintained.

Where the hybrid plants produced are for use as forage or biofuel/biopower feedstock, then it may not be necessary that the flowers of the CMS inbred are fertilized with pollen from a male fertile inbred carrying genes which restore male fertility in the hybrid (F_1) plants. The flowers of the CMS inbred can be fertilized with pollen from a male fertile inbred (such as a B line) chosen for combining ability with the female parent inbred line. Since seed production may not be necessary or even desirable in a high biomass *sorghum* hybrid, there may be no need to use a male inbred line that carries genes which restore male fertility.

This invention also is directed to methods for producing a *sorghum* plant by crossing a first parent *sorghum* plant with a second parent *sorghum* plant wherein the first or second parent *sorghum* plant is a *sorghum* plant of the line R07007. Further, both first and second parent *sorghum* plants can come from the *sorghum* line R07007. Thus, any such methods using the *sorghum* line R07007 are part of this invention: selfing, backcrosses, hybrid production, crosses to populations, and the like. All plants produced using *sorghum* line R07007 as a parent are within the scope of this invention, including those developed from varieties derived from *sorghum* line R07007. Advantageously, the *sorghum* line or hybrid could be used in crosses with other, different, *sorghum* plants to produce the first generation (F_1) *sorghum* hybrid seeds and plants with superior characteristics. The line of the invention can also be used for transformation where exogenous genes are introduced and expressed by the line of the invention. Genetic variants created either through traditional breeding methods using line R07007 or through transformation of R07007 by any of a number of protocols known to those of skill in the art are intended to be within the scope of this invention.

The following describes breeding methods that may be used with line R07007 in the development of further *sorghum* plants. One such embodiment is a method for developing a R07007 progeny *sorghum* plant in a *sorghum* plant breeding program comprising: obtaining the *sorghum* plant, or a part thereof, of line R07007 utilizing said plant or plant part as a source of breeding material and selecting a R07007 progeny

plant with molecular markers in common with R07007 and/or with morphological and/or physiological characteristics selected from the characteristics listed in Tables 1, 2 or 3. Breeding steps that may be used in the *sorghum* plant breeding program include pedigree breeding, back crossing, mutation breeding, and recurrent selection. In conjunction with these steps, techniques such as RFLP-enhanced selection, genetic marker enhanced selection (for example, SSR markers) and the making of double haploids may be utilized.

Another method involves producing a population of hybrid R07007 progeny *sorghum* plants, comprising crossing cultivar R07007 with another *sorghum* plant, thereby producing a population of *sorghum* plants, which, on average, derive 50% of their alleles from cultivar R07007. A plant of this population may be selected and repeatedly selfed or sibbed with a *sorghum* cultivar resulting from these successive filial generations. One embodiment of this invention is the *sorghum* hybrid produced by this method and that has obtained at least 50% of its alleles from line R07007.

One of ordinary skill in the art of plant breeding would know how to evaluate the traits of two plant varieties to determine if there is no significant difference between the two traits expressed by those varieties. For example, see, Fehr and Walt, Principles of Cultivar Development, pp. 261-286 (1987). Thus the invention includes *sorghum* line R07007 progeny *sorghum* plants comprising a combination of at least two R07007 traits selected from the group consisting of those listed in Tables 1, 2, and 3 or the R07007 combination of traits listed in the Summary of the Invention, so that said progeny *sorghum* plant is not significantly different for said traits than *sorghum* line R07007 as determined at the 5% significance level when grown in the same environment. Using techniques described herein, molecular markers may be used to identify said progeny plant as a R07007 progeny plant. Mean trait values may be used to determine whether trait differences are significant, and preferably the traits are measured on plants grown under the same environmental conditions. Once such a line or hybrid is developed its value is substantial since it is important to advance the germplasm base as a whole in order to maintain or improve traits such as yield, disease resistance, pest resistance, and plant performance in extreme environmental conditions.

Progeny of *sorghum* line R07007 may also be characterized through their filial relationship with *sorghum* line R07007, as for example, being within a certain number of breeding crosses of *sorghum* line R07007. A breeding cross is a cross made to introduce new genetics into the progeny, and is distinguished from a cross, such as a self or a sib cross, made to select among existing genetic alleles. The lower the number of breeding crosses in the pedigree, the closer the relationship between *sorghum* cultivar R07007 and its progeny. For example, progeny produced by the methods described herein may be within 1, 2, 3, 4, or 5 breeding crosses of *sorghum* line R07007.

In some embodiments, plants of the inbred *sorghum* variety R07007 can be used as female parents to produce hybrids or as female or male parents to produce new inbred lines. In some embodiments, the inbred *sorghum* variety R07007 can be bred with another inbred *sorghum* (*Sorghum bicolor*) line that also contributes to a high biomass phenotype in the resulting hybrid *sorghum* variety. In other embodiments, the inbred *sorghum* variety R07007 can be used as a parent in breeding with exotic germplasm to make new hybrids and/or inbred lines. Examples of exotic germplasm are wild, weedy, or cultivated *sorghum* species, such as but not limited to, *Sorghum alnum*, *Sorghum amplum*, *Sorghum angustum*, *Sorghum arundinaceum*, *Sorghum bicolor* (such as bicolor,

guinea, caudatum, kafir, and durra), *Sorghum brachypodium*, *Sorghum bulbosum*, *Sorghum burmahicum*, *Sorghum controversum*, *Sorghum drummondii*, *Sorghum ecarinatum*, *Sorghum exstans*, *Sorghum grande*, *Sorghum halepense*, *Sorghum interjectum*, *Sorghum intrans*, *Sorghum laxiflorum*, *Sorghum leiocladum*, *Sorghum macrospermum*, *Sorghum matrankense*, *Sorghum miliaceum*, *Sorghum nigrum*, *Sorghum nitidum*, *Sorghum plumosum*, *Sorghum propinquum*, *Sorghum purpureosericeum*, *Sorghum stipoidesum*, *Sorghum sudanense*, *Sorghum timorese*, *Sorghum trichocladum*, *Sorghum versicolor*, *Sorghum virgatum*, *Sorghum vulgare*, or hybrids such as *Sorghum*×*alnum*, or *Sorghum*×*drummondii*. In some embodiments, the inbred *sorghum* variety R07007 can be used as a parent in breeding with other genera, such as Saccharum.

Single Cross

A single cross hybrid is produced when two inbred lines are crossed to produce the F₁ progeny. Much of the hybrid vigor exhibited by F₁ hybrids is lost in the next generation (F₂). Consequently, seed from hybrid varieties is not typically used for planting stock.

Hybrid *sorghum* can be produced using wind to move the pollen. Alternating strips of the cytoplasmic male sterile inbred (female) and the male fertile inbred (male) are planted in the same field. Wind moves the pollen shed by the male inbred to receptive stigma on the female. Providing that there is sufficient isolation from sources of foreign *sorghum* pollen, the stigma of the male sterile inbred (female) will be fertilized only with pollen from the male fertile inbred (male). The resulting seed, born on the male sterile (female) plants is therefore hybrid and will form hybrid plants that have full fertility restored. In some embodiments, if the hybrid *sorghum* is used as forage or for biomass production, then it may be unnecessary to restore fertility.

Double Cross

A double cross hybrid is produced when two inbred lines are crossed to produce the F₁ progeny, which is then crossed with a third inbred line. This technique can be used to produce forage and high biomass *sorghum* hybrids. Such hybrids typically exhibit greater variability than single cross hybrids. This variability can be an advantage in adaptability across environments

Top Cross

A top cross is a cross between a selection, line, clone etc., and a common pollen parent which may be a variety, inbred line, single cross, etc. The common pollen parent is called the top cross or tester parent. This type of test cross involves mating a series of individuals to a common parent to produce half-sib or full-sib families for evaluation. The test can be used to determine the general combining ability of an individual. Typically, those individuals that perform well in the testcross evaluation are advanced to trials where they are evaluated in crosses with other selected individuals. In *sorghum*, a top cross is commonly an inbred variety cross. In some embodiments, where the top cross is between inbred lines, and the resulting hybrids evaluated exhibit desirable traits, there may be no need for further testing and development, for example, where the resulting hybrids have a high biomass phenotype. In some embodiments, where the top cross is between inbred lines, and the resulting hybrids evaluated exhibit sterility, there may be no need for further testing and development

Pedigree Breeding

Pedigree breeding starts with the crossing of two genotypes, such as *sorghum* linear R07007 and another *sorghum* plant having one or more desirable characteristics that is lacking or which complements *sorghum* line R07007. If the

two original parents do not provide all the desired characteristics, other sources can be included in the breeding population. In the pedigree method, superior plants are selfed and selected in successive filial generations. In the succeeding filial generations the heterozygous condition gives way to homogeneous varieties as a result of self-pollination and selection. Typically in the pedigree method of breeding, five or more successive filial generations of selfing and selection is practiced: F_1 to F_2 ; F_2 to F_3 ; F_3 to F_4 ; F_4 to F_5 ; etc. After a sufficient amount of inbreeding, successive filial generations will serve to increase seed of the developed variety. Preferably, the developed variety comprises homozygous alleles at about 95% or more of its loci.

In addition to being used to create a backcross conversion, backcrossing can also be used in combination with pedigree breeding. As discussed previously, backcrossing can be used to transfer one or more specifically desirable traits from one variety, the donor parent, to a developed variety called the recurrent parent, which has overall good agronomic characteristics yet lacks that desirable trait or traits. However, the same procedure can be used to move the progeny toward the genotype of the recurrent parent but at the same time retain many components of the nonrecurrent parent by stopping the backcrossing at an early stage and proceeding with selfing and selection. For example, a *sorghum* line may be crossed with another *sorghum* line to produce a first generation progeny plant. The first generation progeny plant may then be backcrossed to one of its parent varieties to create a BC_1 or BC_2 . Progeny are selfed and selected so that the newly developed variety has many of the attributes of the recurrent parent and yet several of the desired attributes of the nonrecurrent parent. This approach leverages the value and strengths of the recurrent parent for use in new *sorghum* varieties.

Therefore, an embodiment of this invention is a method of making a backcross conversion of *sorghum* line R07007, comprising the steps of crossing a plant of *sorghum* line R07007 with a donor plant comprising a desired trait, selecting an F_1 progeny plant comprising the desired trait, and backcrossing the selected F_1 progeny plant to a plant of *sorghum* line R07007. This method may further comprise the step of obtaining a molecular marker profile of *sorghum* line R07007 and using the molecular marker profile to select for a progeny plant with the desired trait and the molecular marker profile of *sorghum* line R07007. In one embodiment the desired trait is a mutant gene or transgene present in the donor parent.

Recurrent Selection and Mass Selection

Recurrent selection is a method used in a plant breeding program to improve a population of plants. *Sorghum* line R07007 is suitable for use in a recurrent selection program. The method entails individual plants cross pollinating with each other to form progeny. The progeny are grown and the superior progeny selected by any number of selection methods, which include individual plant, half-sib progeny, full-sib progeny and selfed progeny. The selected progeny are cross pollinated with each other to form progeny for another population. This population is planted and again superior plants are selected to cross pollinate with each other. Recurrent selection is a cyclical process and therefore can be repeated as many times as desired. The objective of recurrent selection is to improve the traits of a population. The improved population can then be used as a source of breeding material to obtain new varieties for commercial or breeding use, including the production of a synthetic cultivar. A synthetic cultivar is the resultant progeny formed by the intercrossing of several selected varieties.

Mass selection is a useful technique when used in conjunction with molecular marker enhanced selection. In mass selection seeds from individuals are selected based on phenotype or genotype. These selected seeds are then bulked and used to grow the next generation. Bulk selection requires growing a population of plants in a bulk plot, allowing the plants to self-pollinate, harvesting the seed in bulk and then using a sample of the seed harvested in bulk to plant the next generation. Also, instead of self pollination, directed pollination could be used as part of the breeding program

Mutation Breeding

Mutation breeding is another method of introducing new traits into *sorghum* line R07007. Mutations that occur spontaneously or are artificially induced can be useful sources of variability for a plant breeder. The goal of artificial mutagenesis is to increase the rate of mutation for a desired characteristic. Mutation rates can be increased by many different means including temperature, long-term seed storage, tissue culture conditions, radiation; such as X-rays, Gamma rays (e.g., cobalt 60 or cesium 137), neutrons (product of nuclear fission by uranium 235 in an atomic reactor), Beta radiation (emitted from radioisotopes such as phosphorus 32 or carbon 14), or ultraviolet radiation (preferably from 2500 to 2900 nm), or chemical mutagens (such as base analogues (5-bromo-uracil), related compounds (8-ethoxy caffeine), antibiotics (streptomycin), alkylating agents (sulfur mustard, nitrogen mustard, epoxides, ethylenamines, sulfates, sulfonates, sulfones, lactones), azide, hydroxylamine, nitrous acid, or acridines. Once a desired trait is observed through mutagenesis the trait may then be incorporated into existing germplasm by traditional breeding techniques. Details of mutation breeding can be found in "Principles of Cultivar Development," Fehr, Macmillan Publishing Company (1993). In addition, mutations created in other *sorghum* plants may be used to produce a backcross conversion of *sorghum* line R07007 that comprises such mutation

Breeding with Molecular Markers

Molecular markers may be used in plant breeding methods utilizing *sorghum* line R07007.

Isozyme Electrophoresis and RFLPs have been widely used to determine genetic composition. See, for example, Dinka, S. J., et al., "Predicting the size of the progeny mapping population required to positionally clone a gene," *Genetics*, 176(4):2035-54 (2007); Gonzalez, C., et al., "Molecular and pathogenic characterization of new *Xanthomonas oryzae* strains from West Africa," *Mol. Plant. Microbe Interact.*, 20(5):534-546 (2007); Jin, H., et al., "Molecular and cytogenetic characterization of an *Oryza officinalis-O. sativa* chromosome 4 addition line and its progenies," *Plant Mol. Biol.*, 62(4-5):769-777 (2006); Pan, G., et al., "Map-based cloning of a novel *sorghum* cytochrome P450 gene CYP81A6 that confers resistance to two different classes of herbicides," *Plant Mol. Biol.*, 61(6):933-943 (2006); Huang, W., et al., "RFLP analysis for mitochondrial genome of CMS-*sorghum*," *Journal of Genetics and Genomics*, 33(4):330-338 (2007); and I. K. Vasil (ed.), *DNA-based markers in plants*, Kluwer Academic Press Dordrecht, the Netherlands.

SSR technology is currently the most efficient and practical marker technology; more marker loci can be routinely used and more alleles per marker locus can be found using SSRs in comparison to RFLPs. Gealy, David, et al., "Insights into the Parentage of *Sorghum*/red Rice Crosses Using SSR Analysis of US Rice Cultivars and Red Rice Populations," *Rice Technical Working Group Meeting Proceedings*, Abstract, p. 179; Lawson, Mark J., et al., "Distinct Patterns of SSR Distribution in the *Arabidopsis thaliana* and rice genomes," *Genome Biology*, 7:R14 (2006); Nagaraju, J., et al., "Genetic Analysis of

Traditional and Evolved Basmati and Non-Basmati *Sorghum* Varieties by Using Fluorescence-based ISSR-PCR and SSR Markers," *Proc. Nat. Acad. Sci. USA.*, 99(9):5836-5841 (2002); and Lu, Hong, et al., "Population Structure and Breeding Patterns of 145 U.S. Rice Cultivars Based on SSR Marker Analysis," *Crop Science*, 45:66-76 (2005). Single Nucleotide Polymorphisms may also be used to identify the unique genetic composition of the invention and progeny varieties retaining that unique genetic composition. Various molecular marker techniques may be used in combination to enhance overall resolution.

Sorghum DNA molecular marker linkage maps have been rapidly constructed and widely implemented in genetic studies. See, Paterson, A. H., *Int. J. Plant Genomics* (2008) 2008: 362451; Rouline A., et al., "Whole genome surveys of rice, maize and *sorghum* reveal multiple horizontal transfers of the LTR-retrotransposon Route66 in Poaceae," *BMC Evol. Biol.* (2009) 9:58; Paterson, A. H., et al., "The *Sorghum bicolor* genome and the diversification of grasses," *Nature* (2009) 457(7229): 551-556; Sasaki, T., et al., "Plant genomics: *sorghum* in sequence," *Nature* (2009) 457(7229): 547-548.

One use of molecular markers is Quantitative Trait Loci (QTL) mapping. QTL mapping is the use of markers, which are known to be closely linked to alleles that have measurable effects on a quantitative trait. Selection in the breeding process is based upon the accumulation of markers linked to the positive effecting alleles and/or the elimination of the markers linked to the negative effecting alleles from the plant's genome. See Winn, J. A., et al. (2009) "QTL mapping of a high protein digestibility trait in *Sorghum bicolor*," *Int. J. Plant Genomics*, 2009:471853, Epub. 2009 Jul. 7.

Molecular markers can also be used during the breeding process for the selection of qualitative traits. For example, markers closely linked to alleles or markers containing sequences within the actual alleles of interest can be used to select plants that contain the alleles of interest during a backcrossing breeding program. The markers can also be used to select for the genome of the recurrent parent and against the genome of the donor parent. Using this procedure can minimize the amount of genome from the donor parent that remains in the selected plants. It can also be used to reduce the number of crosses back to the recurrent parent needed in a backcrossing program. The use of molecular markers in the selection process is often called genetic marker enhanced selection. Molecular markers may also be used to identify and exclude certain sources of germplasm as parental varieties or ancestors of a plant by providing a means of tracking genetic profiles through crosses.

Production of Double Haploids

The production of double haploids can also be used for the development of plants with a homozygous phenotype in the breeding program. For example, a *sorghum* plant for which *sorghum* line R07007 is a parent can be used to produce double haploid plants. Double haploids are produced by the doubling of a set of chromosomes (1N) from a heterozygous plant to produce a completely homozygous individual. For example, see, Wan, et al., "Efficient Production of Doubled Haploid Plants Through Colchicine Treatment of Anther-Derived Maize Callus," *Theoretical and Applied Genetics*, 77:889-892 (1989), and U.S. Pat. No. 7,135,615.

Methods for obtaining haploid plants are also disclosed in Kobayashi, M., et al., *Journ. of Heredity*, 71(1):9-14 (1980); Pollacsek, M., 12(3):247-251, *Agronomie*, Paris (1992); Cho-Un-Haing, et al., *Journ. of Plant Biol.*, 39(3):185-188 (1996); Verdoodt, L., et al., 96(2):294-300 (February 1998); Genetic Manipulation in Plant Breeding, Proceedings International Symposium Organized by EUCARPIA, Berlin, Ger-

many (Sep. 8-13, 1985); Thomas, W J K, et al., "Doubled haploids in breeding," in *Doubled Haploid Production in Crop Plants*, Maluszynski, M., et al. (Eds.), Dordrecht, The Netherlands Kluwer Academic Publishers, pp. 337-349 (2003).

Descriptions of other breeding methods that are commonly used for different traits and crops can be found in one of several reference books (e.g., Allard (1960); Simmonds (1979); Sneep, et al. (1979); Fehr (1987)).

Uses of *Sorghum*

The seed of *sorghum* line R07007, the plant produced from the cultivar seed, the hybrid *sorghum* plant produced from the crossing of the cultivar, hybrid seed, and various parts of the hybrid *sorghum* plant and transgenic versions of the foregoing, can be utilized for human food, livestock feed, biofuel feedstock, biopower feedstock, and as a raw material in industry.

Sorghum is used as livestock feed, a biofuel feedstock, a biopower feedstock, as human food, and as raw material in industry. *Sorghum* grain and plant parts are used as livestock feed. *Sorghum* grain or products therefrom can be consumed by humans and can be used in making an alcoholic beverage. *Sorghum* dry milling products include, for example, grits, meal and flour. Starch and other extracts for food use can be provided by the wet milling process. *Sorghum* starch and flour have application in the paper and textile industries. Other industrial uses include applications in adhesives, building materials and as oil-well muds. Considerable amounts of *sorghum*, both grain and plant material, have been used in industrial alcohol production.

In some embodiments, plants described herein and/or hybrids therefrom have a biomass yield and/or composition that permits efficient processing into free sugars, and subsequently ethanol, for energy production. In some embodiments, such plants provide higher yields of ethanol, butanol, dimethyl ether, cellulosic gasoline, other biofuel molecules, and/or sugar-derived co-products per kilogram of plant material, relative to control plants. By providing improved yields at an equivalent or even decreased cost of production, the plants described herein improve profitability for farmers and processors as well as decrease costs to consumers. Biomass of *sorghum* described herein can also be used in biopower applications in thermal or thermochemical conversion processes to produce energy. In some embodiments, plants described herein and/or hybrids therefrom have a biomass yield and/or composition that permits efficient processing into chopped biomass, pelleted biomass, and/or bricked biomass for biopower production.

Seeds from plants described herein can be conditioned and bagged in packaging material by means known in the art to form an article of manufacture. Packaging material such as paper and cloth are well known in the art. A package of seed can have a label, e.g., a tag or label secured to the packaging material, a label printed on the packaging material, or a label inserted within the package, that describes the nature of the seeds therein.

TABLES

Table 2 and Table 3 provide a comparison of Comparison of inbred *sorghum* R07007 and *sorghum* line BTx631, *sorghum* line ATx2752, and *sorghum* line BTx623. Table 2 shows a comparison of inbred *sorghum* R07007 and *sorghum* line BTx631, *sorghum* line ATx2752, and *sorghum* line BTx623 grown in a winter nursery in 2008-2009 in Puerto

Vallarta, Mexico. Table 3 shows a comparison of inbred *sorghum* R07007 and *sorghum* line BTx631, *sorghum* line ATx2752, and *sorghum* line BTx623 grown in a summer nursery in 2009 in College Station, Tex. The Observations were made on 30 plants spaced approximately 15 cm.

As shown in Table 2, *sorghum* line R07007 has a several traits that are different from *sorghum* line BTx631, *sorghum* line ATx2752, and *sorghum* line BTx623 including leaf mid-rib color, panicle density, rachis branch average, glume awns and seed shape.

TABLE 2

Winter 2008-2009, Puerto Vallarta, Mexico				
Trait	Sorghum Line			
	BTx631	ATx2752	BTx623	R07007
Plant pigment	Tan	Red	Red	Red
Stalk diameter	Mid-Stout	Mid-Stout	Mid-Stout	Mid-Stout
Waxy bloom	Present	Absent	Absent	Absent
Tillers	Few	Few	Moderate	Moderate
Panicle exertion	Short	Short	Long	Short
Degree of senescence				Intermediate
Leaf width	Moderate	Narrow	Moderate	Narrow
Leaf color	Light Green	Light Green	Light Green	Light Green
Leaf margin	Smooth	Wavy	Smooth	Smooth
Leaf altitude	Drooping	Horizontal	Drooping	Drooping
Leaf ligule	Absent	Absent	Absent	Absent
Leaf midrib color	Cloudy	Intermediate	Cloudy	White
Panicle anther color	Light Yellow	Light Yellow	Light Yellow	Light Yellow
Panicle average length (cm)	30	12	15	15
Panicle density	Semi-Open	Compact	Compact	Semi-Compact
Panicle shape	Conical	Cylindrical	Cylindrical	Obovate
Panicle length of central rachis (% of panicle length)	100%	75%	100%	100%
Rachis branches (at grain maturity)	Erect	Erect	Erect	Erect
Rachis branch average	Long	Intermediate	Intermediate	Short
Glumes, length	Intermediate	Intermediate	Short	Intermediate
Glumes, % of grain covered by glume	75%	50%	50%	75%
Glumes, texture		Intermediate		Papery
Glumes, color (at grain maturity)				Light Tan
Glumes, hairiness	Intermediate	Intermediate	Smooth	Intermediate
Glumes, awns	Absent	Absent	Absent	Intermediate
Grain, endosperm color				White
Grain, endosperm type				Starchy
Grain, endosperm texture				Floury
Seed shape	Oval	Oval	Round	Ovate

As shown in Table 3, *sorghum* line R07007 has a several traits that are different from *sorghum* line BTx631, *sorghum* line ATx2752, and *sorghum* line BTx623 including inbred type, the use of the *sorghum*, degree of senescence, mid-rib color, panicle shape, panicle density, rachis branch average, glume texture, glume awns and seed shape.

Tillers	Few	Few	Moderate	Moderate

TABLE 3-continued

Trait	Sorghum Line			
	BTx631	ATx2752	BTx623	R07007
Panicle exertion	Medium	Medium	Long	Medium
Degree of senescence	Senescent	Senescent	Senescent	Intermediate
Leaf width (relative to grain types)	Moderate	Narrow	Moderate	Narrow
Leaf color	Light Green	Light Green	Light Green	Light Green
Leaf margin	Smooth	Wavy	Smooth	Smooth
Leaf altitude	Drooping	Horizontal	Drooping	Drooping
Leaf ligule	Absent	Absent	Absent	Absent
Leaf midrib color	Cloudy	Intermediate	Cloudy	White
Panicle anther color	Light Yellow	Light Yellow	Light Yellow	Light Yellow
Panicle average length (cm)	30	12	15	15
Panicle density	Semi-Open	Compact	Compact	Semi-Compact
Panicle shape	Conical	Cylindrical	Cylindrical	Obovate
Panicle length of central rachis (% of panicle length)	100%	75%	100%	100%
Rachis branches (at grain maturity)	Erect	Erect	Erect	Erect
Rachis branch average	Long	Intermediate	Intermediate	Short
Glumes, length	Intermediate	Intermediate	Short	Intermediate
Glumes, % of grain covered by glume	75%	50%	50%	75%
Glumes, texture	Intermediate	Intermediate	Intermediate	Papery
Glumes, color (at grain maturity)				Light Tan
Glumes, hairiness	Intermediate	Intermediate	Smooth	Intermediate
Glumes, awns	Absent	Absent	Absent	Intermediate
Grain, endosperm color				White
Grain, endosperm type				Starchy
Grain, endosperm texture				Floury
Seed shape	Oval	Oval	Round	Ovate

Deposit Information

A deposit of the Ceres, Inc. and Texas A&M University proprietary Inbred Sorghum R07007 disclosed above and recited in the appended claims has been made with the American Type Culture Collection (ATCC), 10801 University Boulevard, Manassas, Va. 20110. The date of deposit was Nov. 6, 2009. The deposit of 2,500 seeds was taken from the same deposit maintained by Ceres, Inc. since prior to the filing date of this application. All restrictions will be irrevocably removed upon granting of a patent, and the deposit is intended to meet all of the requirements of 37 C.F.R. §§1.801-1.809. The ATCC Accession Number is PTA-10464. The deposit will be maintained in the depository for a period of thirty years, or five years after the last request, or for the enforceable life of the patent, whichever is longer, and will be replaced as necessary during that period.

While a number of exemplary aspects and embodiments have been discussed above, those of skill in the art will recognize certain modifications, permutations, additions and sub-combinations thereof. It is therefore intended that the following appended claims and claims hereafter introduced are interpreted to include all such modifications, permutations, additions and sub-combinations as are within their true spirit and scope.

What is claimed is:

1. A seed of inbred *sorghum* line designated R07007, wherein a representative sample of seed of said line was deposited under ATCC Accession No. PTA-10464.

2. A *sorghum* plant, or a part thereof, produced by growing the seed of claim 1.

3. A *sorghum* plant, or a part thereof, having all the physiological and morphological characteristics of inbred line R07007, wherein a representative sample of seed of said line was deposited under ATCC Accession No. PTA-10464.

4. A tissue culture of cells produced from the plant of claim 2, wherein said cells of the tissue culture are produced from a plant part selected from the group consisting of pollen, glume, panicle leaf, pollen, ovule, cotyledon, hypocotyl, root, root tip, pistil, anther, floret, seed, stalk, immature embryo, and rachis.

5. A *sorghum* plant regenerated from the tissue culture of claim 4, wherein the regenerated plant has all the morphological and physiological characteristics of inbred line R07007, wherein a representative sample of seed of said line was deposited under ATCC Accession No. PTA-10464.

6. A method for producing a hybrid *sorghum* seed wherein the method comprises crossing the plant of claim 2 with a different *sorghum* plant and harvesting the resultant hybrid *sorghum* seed.

7. A hybrid *sorghum* seed produced by the method of claim 6.

8. A method for producing a *sorghum* plant that contains in its genetic material one or more genes, wherein the method comprises crossing the *sorghum* plant of claim 2 with either a second plant of another *sorghum* line which contains a gene or a transformed *sorghum* plant of the inbred *sorghum* line

R07007, so that the genetic material of the progeny that results from the cross contains the gene(s) operably linked to a regulatory element.

9. The method of claim 8 wherein the gene is selected from the group consisting of male sterility, male fertility, herbicide resistance, insect resistance, disease resistance, and water stress tolerance.

10. A *sorghum* plant, or a part thereof, produced by the method of claim 8.

11. The *sorghum* plant of claim 10, wherein the gene confers resistance to an herbicide selected from the group consisting of imidazolinone, sulfonylurea, glyphosate, glufosinate, L-phosphinothricin, triazine and benzonitrile.

12. The *sorghum* plant of claim 10, wherein the gene encodes a *Bacillus thuringiensis* protein.

13. The *sorghum* plant of claim 10, wherein the gene confers disease resistance.

14. The *sorghum* plant of claim 10, wherein the gene confers water stress tolerance.

15. A method for producing a hybrid *sorghum* seed wherein the method comprises crossing the plant of claim 10 with a different *sorghum* plant and harvesting the resultant hybrid *sorghum* seed.

16. A method of introducing a desired trait into inbred *sorghum* line R07007 wherein the method comprises:

- a. crossing the inbred line R07007 plant grown from the inbred line R07007 seed, wherein a representative sample of seed of said line was deposited under ATCC Accession No. PTA-10464, with a plant of another *sorghum* line that comprise a desired trait to produce progeny plants;
- b. selecting progeny plants that have the desired trait to produce selected progeny plants;
- c. crossing the selected progeny plants with the inbred *sorghum* line R07007 plants to produce backcross progeny plants;

d. selecting for backcross progeny plants that have the desired trait and physiological and morphological characteristics of inbred *sorghum* line R07007 listed in Table 1 to produce selected backcross progeny plants; and

e. repeating steps (c) and (d) one or more times in succession to produce selected second or higher backcross progeny plants that comprise the desired trait and the physiological and morphological characteristics of inbred *sorghum* line R07007 as listed in Table 1.

17. The method of claim 16, wherein the desired trait is selected from the group consisting of male sterility, male fertility, herbicide resistance, insect resistance, disease resistance, and water stress tolerance.

18. A *sorghum* plant produced by the method of claim 16, wherein the plant has the desired trait and all of the physiological and morphological characteristics of inbred *sorghum* line R07007 as listed in Table 1.

19. A method for producing inbred *sorghum* line R07007 seed, wherein a representative sample of seed of said line was deposited under ATCC Accession No. PTA-10464, wherein the method comprises crossing a first inbred parent *sorghum* plant with a second inbred parent *sorghum* plant and harvesting the resultant *sorghum* seed, wherein both said first and second inbred *sorghum* plant are the *sorghum* plant of claim 2.

20. A *sorghum* seed, or a part thereof, produced by the method of claim 19.

21. A method for producing a hybrid *sorghum* seed wherein the method comprises crossing the plant of claim 10 with a different *sorghum* plant and harvesting the resultant hybrid *sorghum* seed.

22. A hybrid *sorghum* seed produced by the method of claim 21.
