#### Abstract

Since the discovery of $\left[\mathrm{Mn}_{12} \mathrm{O}_{12}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{16}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]$, research in the area of molecular magnetism has been directed at designing single molecule magnets (SMMs) whose slow paramagnetic relaxation occurs with long relaxation times and at relatively high temperatures. Both polynuclear and mononuclear compounds have been studied with respect to the fundamental characteristics required to make SMMs viable options for device applications including memory storage, spintronics, and quantum computing. In recent years much progress has been made with respect to mononuclear magnets, but approaches that incorporate knowledge of strong anisotropy in exchange coupled systems are still underexplored. Specifically, anisotropic exchange represents an important option for improving the properties of polynuclear SMMs. Despite growing interest in the topic, lack of numerous examples of such systems have hampered progress in this area. This dissertation describes studies of new molecules and synthetic techniques to systematically study conditions that lead to Ising-type anisotropic exchange in heavier transition element molecules.

By drawing on previous work with the cyanometallate moieties $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ and $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$, new precursors and synthetic strategies were developed to aid research in the area of anisotropic exchange interactions. Mo-Ln chains with the formula $\left\{\mathrm{K}\left[\operatorname{Ln}(\operatorname{tmphen})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right\}$ were characterized structurally and magnetically, and revealed that more work could lead to interesting Mo-Ln nanomagnets. A cyanometallate wheel with the formula $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12} \cdot 24 \mathrm{H}_{2} \mathrm{O}$ demonstrated that

incorporating $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ into known architectures can improve magnetic properties. A new, heteroleptic $\mathrm{Mo}^{\mathrm{III}}$ cyanometallate was isolated that will facilitate synthesis of new molecules. Three new compounds that incorporate $\mathrm{Re}^{\mathrm{II}}$ and $\mathrm{V}^{\mathrm{II}}$ demonstrate the requirements for observing anisotropic exchange with $\left[(\operatorname{triphos}) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$. Future work with these strategies will be helpful for investigating the importance of anisotropic exchange as an alternative for the design of single molecule magnets with higher barriers for both the d and f-block elements.

## ACKNOWLEDGEMENTS

I would like to thank Professor Kim Dunbar for providing me with the environment and resources to learn and grow for the last several years. I am tremendously grateful for the space, time, funding, and instruction that I have received from you that helped me develop as a person and a scientist.

I also want to express my thanks to my committee for their support of my research. Professors Tim Hughbanks, David Barondeau, Don Naugle, and Joe Ross, thank you for your time and effort to help me through this process.

Thank you to the Dunbar group for all the support over the years. It has been wonderful working alongside all of you and getting to know the members of this group, including undergraduate students, graduate students, postdocs, visiting scholars, and senior researchers. Thank you to everyone who mentored and supported me during my time here, and I wish you the best for your careers and lives!

Thanks to Professor Greg Powell for helping me my find my passion for science and encouraging me to go to graduate school. I appreciate the support and encouragement that I continue to get from you many years after I left your lab! Thanks for being an excellent mentor and role model.

Thank you to my friends and family (Kempe and Fullerton sides). I deeply appreciate the efforts that everyone made to support and encourage me. Special thanks to my parents, who have provided unconditional support for me over the years. I would not have made it without you.

Most of all, thank you to my wife, Becca, who has stood by me for every bit of this process. Your patience and understanding are incredible. I look forward to many more happy years together.

## CONTRIBUTORS AND FUNDING SOURCES

This work was supervised by a dissertation committee consisting of my advisor Professor Kim Dunbar, and my committee members, Professor Timothy Hughbanks and Professor David Barondeau of the Department of Chemistry, and Professor Donald Naugle of the Department of Physics.

The computational studies in chapter 3 were completed by Dr. Kuduva R. Vignesh, of the Department of Chemistry.

All other work for the dissertation was completed by the student, under the advisement of Kim R. Dunbar of the Department of Chemistry.

This work was also made possible in part by the US Department of Energy under Grant Number DE-SC0012582 and the Robert A. Welch Foundation under Grant Number A-1449. Its contents are solely the responsibility of the authors and do not necessarily represent the official views of the US Department of Energy or the Welch Foundation.

## CHAPTER I

## INTRODUCTION

## Single Molecule Magnetism

In the $21^{\text {st }}$ century, research into the potential applications of nanotechnology, including new types of nanomaterials, has exploded. Molecular magnets have attracted considerable interest from both chemists and physicists since 1993, when single molecule magnet (SMM) behavior was discovered in $\left[\mathrm{Mn}_{12} \mathrm{O}_{12}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{16}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]$ (Figure 1). ${ }^{1-2}$ The structure - first reported in 1980 - is interesting due to the arrangement of $\mathrm{Mn}^{\mathrm{IV}}$ and $\mathrm{Mn}^{\text {III }}$ ions, with four $\mathrm{Mn}^{\mathrm{IV}}$ atoms comprising a cubane-like structure in the core surrounded by the eight acetate-bridged $\mathrm{Mn}^{\text {III }}$ ions in the outer ring. At the time of publication, Lis predicted that if there was significant magnetic communication between the twelve manganese centers in the molecule, the magnetic properties would prove to be interesting. However, further development would have to wait more than a decade. In 1991, EPR and magnetization studies performed by Gatteschi and coworkers corroborated that [ $\left.\mathrm{Mn}_{12} \mathrm{O}_{12}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{16}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]$ has an $\mathrm{S}=10$ ground state and that the sign of the zerofield splitting term, $D$, is negative. ${ }^{3}$ In the same work, AC susceptibility measurements were also performed and it was determined that the out of phase component of the AC susceptibility was frequency dependent, which was previously seen in spin glasses and superparamagnets but had never been observed in a molecular system. Two years later, in 1993, additional work cemented the molecular origin of the phenomenon in $\left[\mathrm{Mn}_{12} \mathrm{O}_{12}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{16}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]$. ${ }^{4-5}$ In particular, the discovery of magnetic hysteresis,

Figure 1. Structure of the molecule $\left[\mathrm{Mn}_{12} \mathrm{O}_{12}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{16}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]$ along the tetragonal axis (c axis). The manganese ions are reported as large grey spheres, oxygen in black, and carbon as small grey spheres. Only oxygen atoms of water molecules have been drawn for the sake of clarity. Reprinted with permission from reference 7, copyright 2006 Oxford University Press.
complete with steps, was convincing evidence that the origin of the effect was molecular in nature. The ability to induce magnetic memory effects in a single molecule was, at the time, unprecedented. These materials, along with single-chain magnets (SCMs), are potentially useful for applications where their small size and magnetic properties could lead to novel uses, such as spin carriers in spintronic devices and quantum computers. ${ }^{6-12}$ The problem with including SMMs or SCMs in devices is that their most interesting property, magnetic memory, only expresses itself at very low temperatures. The blocking temperature, $T_{\mathrm{b}}$, is a value that researchers have used to help compare the molecular

Figure 2. Structure of $\left[\left(\mathrm{Cp}^{\mathrm{iPr} 5}\right) \mathrm{Dy}\left(\mathrm{Cp}^{*}\right)\right]^{+}$, the SMM with the highest known $T_{\mathrm{b}}$ to date, and the relaxation mechanism of the complex. Blue arrows show the most probable relaxation pathway, while red arrows show other pathways with non-negligible contributions. Adapted with permission from reference 13, copyright 2018 American Association for the Advancement of Science.
magnets by quantifying the magnetic memory effect. $T_{\mathrm{b}}$ defined as either the highest observed temperature for magnetic hysteresis or the temperature at which the magnetic relaxation time, $\tau$, equals 100 s for a particular $\mathrm{SMM} .{ }^{7}$ The $T_{\mathrm{b}}$ value is $\sim 4 \mathrm{~K}$ for $\mathrm{Mn}_{12}-$ acetate $^{1}$ and 80 K for the current record-holding molecule, $\left[\left(\mathrm{Cp}^{\mathrm{iPr} 5}\right) \mathrm{Dy}(\mathrm{Cp} *)\right]^{+}\left(\mathrm{Cp}^{\mathrm{iPr}}=\right.$ penta-iso-propylcyclopentadienyl, $\mathrm{Cp}^{*}=$ pentamethylcyclopentadienyl). ${ }^{13}$ Also shown in Figure 2 are the relaxation pathways that constitute the barrier to reversal of the magnetization in $\left[\left(\mathrm{Cp}^{\mathrm{iPr} 5}\right) \mathrm{Dy}\left(\mathrm{Cp}^{*}\right)\right]^{+}$. This barrier between the spin pointing up or pointing down is the key characteristic that allows molecules to function as SMMs. While classical magnets also have barriers to reversal of the magnetization, the origin of that barrier is different for SMMs. To help explain that difference, it is helpful to make a side-by-side comparison of classical magnets and SMMs.

In a typical bulk magnet, the spins are organized into magnetic domains, areas where the spins are aligned along a common axis. Domain walls - areas where the spins are intermediate between two domains - split the domains within this material, but the walls themselves have a finite thickness. When a sufficient field is applied, the domain that aligns with that field grows (by moving the domain walls) until it dominates the majority of the magnet's area, giving rise to the net magnetic moment of the material. One of the key measurements that can be used to verify the existence of magnetic memory is the measurement of magnetic hysteresis. In this measurement, the sample is placed in a magnetic field that is swept positive to negative and back along a single direction. In materials that exhibit magnetic memory, the material will stay magnetized even when there is no applied field. In bulk magnets, there can be steps in the hysteresis loop as domain walls change size and move to minimize the magnetic energy in the sample (Figure 3). ${ }^{7,14}$ When the particle is so small that it can no longer accommodate domain walls, the entire particle adopts a single domain. For these "single domain particles," hysteresis loops do not have well-pronounced steps because the spins are compelled to flip as a unit or not at all. As shown in Figure 3, SMMs also exhibit magnetic hysteresis. The origin of the magnetic behavior in SMMs, however, is distinct from that of classic magnets. Magnetic memory arises because of an energy barrier to

reversal of the magnetization. In bulk magnets, that energy barrier is linked to the large number of spins that communicate with each other in the material. In both multidomain and single domain magnets, cooperativity is key to understanding the data. Each spin has a local magnetic field that exerts magnetic force on its neighbors, making alignment of their magnetic axes energetically favorable. These interactions between spins are the origin of the barrier to reversal of the magnetization. But in SMMs, each molecular spin carrier has magnetic anisotropy that arises from its own electronic environment, meaning that they have a fundamentally different origin to their magnetic behavior than classical magnets. As seen in Figure 3, there are steps in the hysteresis loops of SMMs; these steps
imply that the magnets can flip independently of each other. While single domain particles are compelled to act as a unit due to the lack of domain walls, SMMs have no such restriction. Rather than originating from the cooperativity between spin carriers, the barrier in most transition metal SMMs such as $\left[\mathrm{Mn}_{12} \mathrm{O}_{12}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{16}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]$ (those that have only quenched or second order spin-orbit coupling) is defined as $\mathrm{U}=S^{2}|D|$ or $\mathrm{U}=$ $1 / 2 S^{2}|D|$ for integer and half-integer spin systems, respectively, where $S$ is the ground state spin and $D$ is the axial zero-field splitting parameter. The parameter $D$ typically has a negative value in SMMs. A negative value of $D$ imparts axial anisotropy to the magnetic moment, giving it a directional bias along one axis. The energy barrier responsible for the magnetic memory effect is a barrier between the moment pointing up or down along that easy axis. So, in SMMs, the origin of the barrier is present in each and every SMM, rather than being a result of the collection of spin carriers. Each spin carrier has local anisotropy and its own spin that can respond independently to the environment. While this fundamental difference in the origin of magnetic behavior is interesting, the low temperature necessary to observe this behavior imposes a significant restriction on implementation of SMMs in technological applications. As mentioned above, the record $T_{\mathrm{b}}$ for molecular magnets remains 80 K , barely higher than the boiling temperature of liquid nitrogen. Finding molecules with higher $T_{\mathrm{b}}$ would help propel research forward in this area.

There are three main parameters that help researchers compare SMMs: $T_{\mathrm{b}}$ - which was mentioned above, $U$ - the theoretical size of the barrier to reversal of magnetization, and $U_{\text {eff }}$ - the observed barrier to reversal of the magnetization. $U_{\text {eff }}$ is always smaller than

U in SMMs. SMMs typically do not perform as well as the parameter $U$ would suggest because U does not adequately address the full complexity of magnetic relaxation in nanomagnets. $U$ describes what is known as the "thermal barrier" to relaxation of the magnetization, but there are other mechanisms by which SMMs can reverse their magnetization. One of the most significant of these is quantum tunneling of the magnetization (QTM), which limits the performance of SMMs by allowing spins to tunnel through the barrier. This can happen only when a pair of degenerate states, one of each side of the barrier, exists so that the magnetization can tunnel between the two. The phenomenon of quantum tunneling explains why "steps" exist in the hysteresis loops of SMMs; only some magnetic fields meet the requisite conditions for tunneling to occur. Quantum tunneling and other non-thermal relaxation mechanisms result in a measured $\mathrm{U}_{\text {eff }}$ that is lower than U . Nonetheless, efforts to increase the barrier height have been a major focus in the field of nanomagnets. Because of the exponential dependence of the barrier on $S$, early research focused on making large molecules with the largest ground spin state possible. The molecule with the largest spin ground state known to date is $\left[\mathrm{Mn}^{\mathrm{III}}{ }_{12} \mathrm{Mn}^{\mathrm{II}}{ }_{7}\left(\mu_{4} \mathrm{O}\right)_{8}\left(\mu_{3}, \eta^{1} \mathrm{~N}_{3}\right)_{8}(\mathrm{~L})_{12}(\mathrm{MeCN})_{6}\right] \mathrm{Cl}_{2} \cdot 10 \mathrm{MeOH} \cdot \mathrm{MeCN} \quad(\mathrm{L}=2,6$-bis-(hydroxy-methyl)-4-methylphenol) with a $S=83 / 2 .{ }^{15}$ The largest spin ground state for a cyanide-bridged molecule is $S=31$, held by the molecule $\left[\mathrm{Mn}(\mathrm{dpop})\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]_{2}-$ $\left[\left\{\mathrm{Mo}(\mathrm{CN})_{7}\right\}_{8}\{\mathrm{Mn}(\text { dpop })\}_{10}\left\{\mathrm{Mn}(\text { dpop })\left(\mathrm{H}_{2} \mathrm{O}\right)\right\}_{4}\right] \cdot \mathrm{xH}_{2} \mathrm{O} \quad$ (dpop $\quad=\quad$ 2,13-dimethyl-3,6,9,12,18-pentaazabicyclo-[12.3.1]octadeca-1(18),2,12,14,16-pentaene) prepared in the Dunbar group (Figure 4). ${ }^{16}$ Despite the impressive $S$ values for such molecules, neither of these two molecules exhibit SMM behavior. A paper published by Oliver Waldmann

Figure 4. Structures of some notable molecules with large spin ground states. Left: structure of $\left[\mathrm{Mn}^{\mathrm{III}}{ }_{12} \mathrm{Mn}^{\mathrm{II}} 7\left(\mu_{4} \mathrm{O}\right)_{8}\left(\mu_{3}, \eta^{1} \mathrm{~N}_{3}\right)_{8}(\mathrm{~L})_{12}(\mathrm{MeCN})_{6}\right]^{2+}$. explains why maximizing $S$ is not a generally successful strategy for making high temperature SMMs. ${ }^{17} D$ and $S$ are not truly independent variables; $D$ is inversely proportional to $S$ so that $\mathrm{U}_{\mathrm{eff}}$, the observed barrier, is proportional to $S^{0}$. Waldmann notes that researchers who focused on increasing the value of $D$ were seeing more success in raising $T_{\mathrm{b}}$, which helped shift the focus of the field. Later, a groundbreaking paper from the Ruiz research group elucidated the origin of $D$ and extrapolated their prediction to all first-row transition metals. ${ }^{18}$ There has been incredible progress in this line of work from synthetic groups and computational groups, leading to new transition metal magnets that outperform the earliest examples. ${ }^{19-20}$ However, the predictions by Ruiz and coworkers are limited to first-row transition metals. The story is more complicated for metal centers with significant spin-orbit coupling, such as heavier transition metals and f-block metals.

The anisotropy in compounds with these heavy metals can no longer be properly described by $S$ and $D$; they have first order spin-orbit coupling such that spin is no longer a good quantum number, so the magnetic states are better described in terms of $M_{\mathrm{J}}$ levels. ${ }^{21}$ Much of the recent work in the field focused on lanthanides, which have significant spin-orbit coupling, complicating the interpretation of their magnetic properties. ${ }^{22}$ The shift to lanthanide chemistry, though, does extend and improve the work on mononuclear SMMs, since a single lanthanide center often has significantly improved magnetic properties than a single transition metal center. Most record-holding compounds are lanthanide based, and many have only one metal center. Research into polynuclear compounds, however, could provide new insights into how to build high temperature SMMs that may be suitable for technological applications. In this work, particular attention will be paid to polynuclear structures bridged by cyanide.

## Cyanide Ligand and the Building Block Approach

One ligand that has a long history of mediating relatively strong and predictable exchange between metal centers is cyanide. As a result, cyanide-bridged materials have been a staple of molecular magnetism almost since its inception. Some of the most impressive extended networks in magnetism are Prussian Blue analogues, which are infinite networks composed of divalent and trivalent metal centers bridged by cyanide. Arguably the most impressive compound of this type, $\mathrm{V}^{\mathrm{II}}\left[\mathrm{Cr}^{\mathrm{II}}(\mathrm{CN})_{6}\right]_{0.86} \cdot 2.8 \mathrm{H}_{2} \mathrm{O}$, exhibits magnetic ordering above room temperature. ${ }^{23}$ In order to utilize these properties for applications, it is necessary to understand them at a basic level. The spin Hamiltonian
proposed by Heisenberg, Dirac, and Van Vleck is the Hamiltonian that we still use today to understand most coupling between two metal centers:

$$
\text { (1) } \mathcal{H}=-2 J S_{\mathrm{M}} S_{\mathrm{M}^{\prime}}
$$

where $J$ is the magnitude of the magnetic interaction between the two spins $S_{\mathrm{M}}$ and $S_{\mathrm{M}^{\prime}}$. When $J$ is positive, the coupling is ferromagnetic (the spins align parallel to each other) and when $J$ is negative, the coupling is antiferromagnetic (the spins align antiparallel to each other). Larger $J$ values necessarily mean that the energy gap between magnetic states is larger i.e. the interaction is stronger between those spins. Cyanide mediates this coupling because its orbitals overlap with the magnetic orbitals on $S_{\mathrm{M}}$ and $S_{\mathrm{M}^{\prime}}$. This phenomenon is known as superexchange in cases where the bridging ligand is diamagnetic. ${ }^{24-25}$ When the symmetry of the magnetic orbitals is such that they can mix with the same orbital on the $\mathrm{CN}^{-}$ligand, this results in antiferromagnetic exchange. If the mixing is symmetry forbidden, then the result is ferromagnetic coupling (Figure 5). These simple rules, known generally as the "Goodenough-Kanamori rules" can be used to rationalize superexchange and are particularly effective in the case of cyanide-bridged complexes. In large compounds, the complexity of the Hamiltonian increases as a function of the number of magnetic centers:

$$
\text { (2) } \mathcal{H}=\Sigma\left[-2 J_{i j}\left(S_{\mathrm{M}}\right)_{i}\left(S_{\mathrm{M}^{\prime}}\right)_{j}\right]
$$

However, the symmetry of the structure often simplifies the expression, in practice. For metal pairs that are symmetry equivalent, the same $J$ is often used to describe the coupling between those pairs. Large values of $J$ lead to a more isolated ground state in the molecule,

Figure 5. Depiction of the orthogonality principle in cyanide-bridged compounds. Top: symmetry allowed overlap leads to antiferromagnetic exchange due to paired spins. Bottom: orthogonal magnetic orbitals lead to ferromagnetic exchange.
which is important for magnetic properties in polynuclear compounds because it mitigates the population of excited states. Compounds with large coupling and appropriate anisotropy can exhibit SMM behavior - although since the community began focusing on maximizing the anisotropy of single metal atoms, fewer examples of polynuclear SMMs are being reported. Nonetheless, some design principles have emerged. In the series with the formula $\left[\mathrm{L}_{\mathrm{NNN}} \mathrm{CoLnCoL}_{\mathrm{NNN}}\right] \mathrm{NO}_{3}\left(\mathrm{~L}=\mathrm{N}, \mathrm{N}^{\prime}, \mathrm{N}^{\prime \prime}\right.$-tris(2-hydroxy-3-methoxy-

benzili-dene)-2-(aminomethyl)-2-methyl-1,3-propanediamine; $\mathrm{Ln}=\mathrm{Gd}, \mathrm{Tb}, \mathrm{Dy}$ ), ${ }^{26-27}$ all three compounds in the series are SMMs , but $\left[\mathrm{L}_{\mathrm{NNN}} \mathrm{CoGdCoL}_{\mathrm{NNN}}\right] \mathrm{NO}_{3}$ is the best SMM (Figure 6). The authors of the work conclude that the isotropic nature of Gd makes it the best match to the anisotropic Co centers. For the Tb and Dy analogues, the conflicting magnetic axes of the lanthanide and Co ions interfere with the anisotropy barrier to reversal of the magnetization. While this realization is valuable, these particular compounds are not particularly impressive examples of SMMs. Increased coupling and a better source of anisotropy would certainly lead to better results.

Anisotropic exchange has emerged as a strategy to improve the properties of polynuclear SMMs by introducing anisotropy to the coupling, rather than relying on localized sources of single ion anisotropy. ${ }^{21,28-30}$ Anisotropic exchange is not a novel phenomenon, but very few SMMs that exhibit this specific kind of exchange exist. Despite
its rarity, it is possible to intentionally design molecules that exhibit anisotropic exchange. ${ }^{31}$ The most important requirement is the existence of an orbitally degenerate electronic ground state for a metal center with significant spin-orbit coupling. In orbitally degenerate compounds, the first order spin-orbit interaction renders $S$ an invalid quantum number. The magnetic properties of these building blocks are often described in terms of pseudo-spin states and fictitious spins to simplify the explanation while acknowledging the limitations of $S$ in that context. Coupling that involves such a metal center splits $J$ into $J_{x}, J_{y}$, and $J_{z}$. When $J_{z}$ is large and $J_{x} \approx J_{y} \approx 0$, the anisotropic coupling gives rise to an easy axis in a distinctly different way than $D$ does for mononuclear transition metal SMMs. This easy-axis anisotropy is referred to as "Ising type" anisotropy. Since the barrier originates from $J_{z}$, its height is also dependent on the magnitude of the coupling. Theoretically, stronger coupling leads to a larger barrier in anisotropically coupled systems, but there are not yet experimental results to back up this claim. It is important to study molecules that exhibit this type of anisotropy in detail to determine its potential for developing high temperature SMMs. Because the primary requirement for anisotropic exchange is an orbitally degenerate metal center, it is possible to take advantage of the building block approach ${ }^{32-33}$ to make these types of SMMs.

The central idea of the building block approach is using discrete compounds as components of a larger structure. Cyanide chemistry represents this approach very well, as cyanometallates are stable and constitute excellent linkers for polynuclear compounds. Many geometries can be accessed for a single cyanometallate based solely on the shape and denticity of the blocking ligands on the second metal complex (Figure 7). Pairing two

Figure 7. Schematic diagram showing possible structures from reactions of a hexacyanometallate and a metal complex with a pentadentate blocking ligand. building blocks that will form a specific geometry allows one to design a structure that takes advantage of each component's unique properties. This strategy is especially attractive from the perspective of engendering anisotropic exchange; the ability to choose an orbitally degenerate building block greatly simplifies many of the key challenges when designing systems that exhibit Ising-type anisotropic exchange. Two building blocks that have been previously used in the Dunbar group are standout candidates for this strategy, namely $\quad\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ and $\quad\left[(\text { triphos }) \mathrm{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-} \quad$ (triphos $\quad=$ 1,1,1Tris(diphenylphosphinomethyl)ethane). What makes these building blocks good candidates for engendering anisotropic exchange is their orbitally degenerate ground state and the presence of cyanide ligands that allow for reliable coordination to other metal centers. These compounds have been used to synthesize impressive molecules with interesting magnetic properties. ${ }^{16,34-39}$ However, most of these molecules do not have the ideal geometry for maximizing anisotropic exchange. Thus, one of the major thrusts of research on anisotropic exchange-coupled complexes is the development of reliable methods to synthesize compounds with the correct geometry for Ising-type anisotropic exchange. The requirements for Ising-type anisotropic exchange vary by building block, so the explanations must be treated as separate cases.

The main goal for designing SMMs that incorporate $\left[\mathrm{Mo}^{\text {III }}(\mathrm{CN})_{7}\right]^{4-}$ is to maintain an undistorted pentagonal bipyramidal arrangement of $\mathrm{CN}^{-}$ligands and to coordinate metal complexes to the apical $\mathrm{CN}^{-}$ligands. For $\mathrm{Mo}^{\text {IIII }}$, with its $\mathrm{d}^{3}$ electron count, pentagonal bipyramidal symmetry leads to an orbitally degenerate pseudo- $S=1 / 2$ ground state (Figure 8). If that symmetry is broken, the orbital degeneracy is quenched and anisotropic
exchange will be minimized or quenched. Evidence for this claim can be found in the molecules $\left[\mathrm{Mn}\left(\mathrm{L}_{1}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)\right]_{2}\left[\mathrm{Mo}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ and $\left[\mathrm{Mn}\left(\mathrm{L}_{1}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)\right]_{2}[\mathrm{Mn}(\mathrm{L})]_{2}\left[\mathrm{Mo}(\mathrm{CN})_{7}\right]_{2}$ (Figure 9). ${ }^{39}$ These molecules are interchangeable by the addition and removal of water in the crystals, but, while the former trinuclear molecule exhibits SMM behavior, the latter hexanuclear one does not, despite theoretical predictions that these ladder-type compounds should exhibit better magnetic behavior than their trinuclear counterparts. ${ }^{40}$ The lack of SMM behavior in the hexanuclear molecule occurs because the distortion of the pentagonal bipyramid of $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ quenches the orbital degeneracy of that moiety and eliminates the easy axis of magnetization. The coordination of metal centers to the axial cyanide ligands is equally important, as shown by the three compounds $\left[\mathrm{Mn}\left(\mathrm{L}_{\mathrm{N} 5 \mathrm{Me}}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)\right]_{2}\left[\mathrm{Mo}(\mathrm{CN})_{7}\right] \cdot 6 \mathrm{H}_{2} \mathrm{O}\left(\mathrm{L}_{\mathrm{N} 5 \mathrm{Me}}=2,2^{\prime}-\left(\left(\left(1 E, 1^{\prime} E\right)\right.\right.\right.$-pyridine-2,6-diylbis(ethan1 -yl-1-ylidene))bis(azaneylylidene))bis( $N$-methylethan-1-amine), $\quad\left[\mathrm{Mn}^{\mathrm{II}}\left(\mathrm{L}_{\mathrm{N} 3 \mathrm{O} 2}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)\right]_{2}-$ $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot 7 \mathrm{H}_{2} \mathrm{O} \quad\left(\mathrm{L}_{\mathrm{N} 302}=(2 E, 12 E)\right.$-2,13-dimethyl-6,9-dioxa-3,12-diaza-1(2,6)-pyridinacyclotridecaphane-2,12-diene $)$, and $\left[\operatorname{Mn}\left(\mathrm{L}_{\mathrm{DAPSC}}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)\right]_{2}\left[\mathrm{Mo}(\mathrm{CN})_{7}\right]$ $\left.\cdot 6 \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{MeCN}\right] \quad\left(\mathrm{L}_{\text {DAPSC }}=\left(2 E, 2^{\prime} E\right)-2,2^{\prime}-(\right.$ pyridine-2,6-diylbis(ethan-1-yl-1-ylidene) $)-$ bis(hydrazine-1-carboxamide) (Figure 10)..$^{38}$ The latter two compounds have $\mathrm{Mn}^{\mathrm{II}}$ coordinated to the apical cyanide ligands of $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ and exhibit no SMM behavior, while the former has $\mathrm{Mn}^{\mathrm{II}}$ coordinated to the apical cyanide ligands and shows the highest temperature hysteresis loops for any cyanide-bridged SMM compound. Theoretical work shows that coupling to apical $\mathrm{CN}^{-}$ligands of $\left[\mathrm{Mo}^{\text {III }}(\mathrm{CN})_{7}\right]^{4-}$ can induce Ising-like anisotropic exchange. ${ }^{28}$ If the anisotropic exchange has sufficient contribution from $J_{\mathrm{xy}}$, then an easy axis does not develop and SMM behavior is not observed. As shown with the

Figure 8. molecules in Figure 10, even changes to the ligands on the 3d metal can change the coordination geometry in unpredictable ways. Thus, the biggest barrier to creating better SMMs with $\left[\mathrm{Mo}^{\text {III }}(\mathrm{CN})_{7}\right]^{4-}$ is the synthetic challenge involved. In the subsequent chapters, this work will demonstrate those challenges through the lens of some reactions of $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ and propose some guidelines for improving the SMM behavior of molecules that incorporate this moiety. This work also introduces a new building block, $\left[\mathrm{Mo}^{\text {III }}(\mathrm{DAPB})(\mathrm{CN})_{2}\right]^{-}\left(\mathrm{DAPBH}_{2}=\right.$ diacetylpyridinebis(benzoylhydrazone)) that may improve the properties of future $\mathrm{Mo}^{\text {III }}$-based exchange coupled systems by imposing a pentagonal bipyramidal geometry on $\mathrm{Mo}^{\text {III }}$ that is more rigid than the geometry in $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$.

The moiety $\left[(\text { triphos }) \operatorname{Re}^{\text {II }}(\mathrm{CN})_{3}\right]^{-}$has different requirements than $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ for Ising-type anisotropic exchange. Due to the influence of the trigonal crystal field, the ground state of $\left[(\right.$ triphos $\left.) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]$ is orbitally degenerate, ${ }^{34}$ allowing for the observation of spin-orbit coupling. The small separation of the ground state and the first excited state also leads to a large amount of temperature independent paramagnetism (TIP) in all reported compounds of $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$. The only reported SMMs that contain this moiety are the molecular cube $\left[\left\{\mathrm{MnCl}_{4}\left\{\operatorname{Re}(\text { triphos })(\mathrm{CN})_{3}\right\}_{4}\right]\right.$ and the trigonal bipyramidal molecules $\left(\mathrm{Et}_{4} \mathrm{~N}\right)_{2}\left[\left((\operatorname{triphos}) \operatorname{Re}(\mathrm{CN})_{3}\right)_{2}\left(\operatorname{Ln}\left(\mathrm{NO}_{3}\right)_{3}\right)_{3}\right] \cdot 4 \mathrm{MeCN}(\mathrm{Ln}=\mathrm{Dy}$, Tb). ${ }^{36-37,41}$ The trigonal bipyramidal molecules are understood to be SMMs based solely on the magnetic properties of the lanthanide ions; the rhenium center does not significantly contribute to those properties. In the molecular $\mathrm{Mn}_{4} \mathrm{Re}_{4}$ cube, which is the first known example of a 5d transition metal SMM, anisotropic exchange is responsible for the

Figure 11. Left: Plot of $\left[\{\mathrm{MnCl}\}_{4}\left\{\operatorname{Re}(\text { triphos })(\mathrm{CN})_{3}\right\}_{4}\right]$ with thermal ellipsoids drawn at the $25 \%$ probability level. observed SMM behavior. ${ }^{29}$ Magnetic axes develop on the C3 axis of each $\left[(\text { triphos }) \mathrm{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$moiety, so each diagonal of the cube has a magnetic axis (Figure 11). The net magnetic moment in the ground state is significantly reduced due to partial cancellation of those individual magnetic moments. Theoretically, SMM properties of a molecule that incorporates $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$could be improved by ensuring that anisotropic exchange occurs along one unique axis in a molecule. To date, there are no molecules that incorporate this building block with strong coupling and all $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$sharing one magnetic axis. This work will show that it is possible to synthesize such a compound and provides evidence that such a strategy will lead to new advanced in the area of anisotropic exchange coupled systems.

## CHAPTER II

## CYANIDE BRIDGED CHAINS OF LANTHANIDE AND MOLYBDENUM IONS

## Background

While the attention and focus on SMMs has occupied much of the work in the field of molecular magnetism, significant work has also been carried out in the area of single chain magnets (SCMs). SCMs were first proposed by Glaber in $1963^{42}$ and finally realized by Gatteschi and coworkers in $2001 .{ }^{43}$ SCMs are excellent candidates to study the effects of magnetic coupling and anisotropy on magnetic behavior and also offer an opportunity to study multi-functionality through optical, conducing, and other properties. ${ }^{44-45}$ Like SMMs, SCMs can be made using a variety of strategies. They can be made from one building block or multiple building blocks; as long as the magnetic units in the chain communicate via exchange, there is a chance to observe interesting properties. Notably, the anisotropy in the chain can be different from the anisotropy of the building blocks. In the case of catena- $\left[\mathrm{Fe}^{\mathrm{II}}\left(\mathrm{ClO}_{4}\right)_{2}\left\{\mathrm{Fe}^{\mathrm{III}}(\mathrm{bpca})_{2}\right\}\right] \mathrm{ClO}_{4}$, the selected building blocks exhibit easy-plane anisotropy, but the resulting chain has easy-axis anisotropy, which the authors attribute to the twisting of the easy planes with respect to each other (Figure 12). ${ }^{46}$ Because of the difficulty in predicting how building blocks with arrange themselves in a 1 D chain, it is challenging to predict the resulting magnetic properties. As such, it is important to investigate 1D chains with different types of building blocks.

Figure 12. Structure of catena- $\left[\mathrm{Fe}^{\mathrm{II}}\left(\mathrm{ClO}_{4}\right)_{2}\left\{\mathrm{Fe}^{\mathrm{III}}(\mathrm{bpca})_{2}\right\}\right] \mathrm{ClO}_{4}$ and spin arrangment of the high-spin $\mathrm{Fe}^{\text {II }}$ and low-spin $\mathrm{Fe}^{\text {III }}$ centers contained therein. The $\mathrm{O}_{\mathrm{A}}$ and $\mathrm{O}_{\mathrm{B}}$ labels show the two different types of oxygen ligands for the high spin $\mathrm{Fe}^{\mathrm{II}}$ centers. Reproduced with permission from reference 46, copyright 2005 American Chemical Society.

In the case of SCMs, often there is one cyanide containing building block and one other metal center, in order to take advantage of the cyanide ligand's ability to mediate magnetic coupling. While many cyanide-bridged SCMs have been made using octahedral cyanometallates, ${ }^{47-52}$ there are none reported that utilize a 7 -coordinate derivative. This is an important area because 7-coordinate geometries can lead to unexpected arrangements of atoms, which, as shown above, can heavily influence the behavior of the resulting chain. While there are a number of 3 D and 2 D coordination polymers that incorporate $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-},{ }^{53-65}$ there are no reported 1D chains that incorporate this anion. Many of
those reports note that the seven coordinate structure of $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ reduces the symmetry present in the system as compared to six-coordinate cyanometallates that are frequently used in preparation of these Prussian Blue analogs. The lower symmetry leads to increased anisotropy and more interesting magnetic properties. Those qualities provide a solid rationale for looking into the synthesis of new 1D chains that incorporate $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$. Our group previously reported a variety of lanthanide-3d chains that provided us with inspiration for this work. We decided to synthesize new compounds analogous to $\left\{\left[\mathrm{Sm}(\text { tmphen })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Fe}(\mathrm{CN})_{6}\right] \cdot \mathrm{MeOH} \cdot 13 \mathrm{H}_{2} \mathrm{O}\right\}_{\infty}$ and $\left\{\left[\mathrm{Sm}(\text { tmphen })_{2}-\right.\right.$ $\left.\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Cr}(\mathrm{CN})_{6}\right] \cdot \mathrm{MeOH} \cdot 9 \mathrm{H}_{2} \mathrm{O}\right\}_{\infty}($ tmphen $=3,4,7,8$-tetramethyl-1,10-phenanthroline) $) .{ }^{66}$ These compounds (Figure 13) were found to exhibit ferromagnetic exchange between the 3d and 4 f metal centers and showed signs of glassy behavior. With similar conditions using $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$, it may be possible to observe SCM behavior, particularly if anisotropic exchange can be induced between the orbitally degenerate $\mathrm{Mo}^{\text {III }}$ center and the lanthanide ion. As a result of this work, a new series of chains with the formula $\left\{\mathrm{K}\left[\operatorname{Ln}(\text { tmphen })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right.$ was synthesized to investigate the effect of installing $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ in a 1D magnetic chain.

Figure 13. Thermal ellipsoid plots of $\left\{\left[\mathrm{Sm}(\mathrm{tmphen})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Fe}(\mathrm{CN})_{6}\right] \cdot \mathrm{MeOH} \cdot 13 \mathrm{H}_{2} \mathrm{O}\right\}_{\infty}$ (left) and $\left\{\left[\operatorname{Sm}(\text { tmphen })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Cr}(\mathrm{CN})_{6}\right] \cdot \mathrm{MeOH} \cdot 9 \mathrm{H}_{2} \mathrm{O}\right\}_{\infty}$ (right) drawn at the $50 \%$ probability level. The atoms from solvent molecules have been omitted for the sake of clarity. Reproduced with permission from reference 66, copyright 2007 Royal Society of Chemistry.

## Experimental Details

## Synthesis

Syntheses were performed under air free conditions in a nitrogen filled glove box. Solvents were deoxygenated by sparging with argon gas on a Schlenk line. $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]$ - $2 \mathrm{H}_{2} \mathrm{O}$ was synthesized using literature methods. ${ }^{67}$ All other chemicals were used as received from commercial sources.
$\left\{\mathrm{K}\left[\operatorname{Gd}(\text { tmphen })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right\}(\mathbf{1})-47 \mathrm{mg}$ tmphen $(0.2 \mathrm{mmol})$ and 37 mg $\mathrm{GdCl}_{3}$ ( 0.1 mmol , anhydrous basis) were dissolved in a mixture of $2 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}, 2 \mathrm{~mL}$ DMF, and 1 mL MeCN . This solution was added dropwise to a solution of $50 \mathrm{mg}(0.1 \mathrm{mmol})$ sample of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ dissolved in $2 \mathrm{~mL} \mathrm{H} \mathrm{H}_{2} \mathrm{O}$ and 2 mL DMF. The yellow solution of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ gradually turned orange over the course of the addition. After being left to stand overnight, X-ray quality dark orange crystals were harvested by filtration and washed with DMF and $\mathrm{Et}_{2} \mathrm{O}, 20 \mathrm{mg}, 20 \%$ yield. Samples were dried under
vacuum prior to submission for elemental analysis and SQUID measurements. Found: C, 46.45; H, 4.47; N, 15.66\%. Calculated for $\left\{\mathrm{K}\left[\mathrm{Gd}(\operatorname{tmphen})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right\} \cdot 2 \mathrm{H}_{2} \mathrm{O} \cdot$ MeCN: C, 46.45; H, 4.09; N, 15.85\%.
$\left\{\mathrm{K}\left[\mathrm{Tb}(\text { tmphen })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\text {III }}(\mathrm{CN})_{7}\right]\right\}(\mathbf{2})-47 \mathrm{mg}$ tmphen $(0.2 \mathrm{mmol})$ and 37 mg $\mathrm{TbCl}_{3}$ ( 0.1 mmol , anhydrous basis) were dissolved in a mixture of $2 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}, 2 \mathrm{~mL}$ DMF, and 1 mL MeCN . This solution was added dropwise to a solution of $50 \mathrm{mg}(0.1 \mathrm{mmol})$ sample of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\text {III }}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ dissolved in $2 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}$ and 2 mL DMF. The yellow solution of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ gradually turned orange over the course of the addition. After being left to stand overnight, X-ray quality dark, orange crystals were harvested by filtration and washed with DMF and $\mathrm{Et}_{2} \mathrm{O}, 23 \mathrm{mg}, 23 \%$ yield. Samples were dried under vacuum prior to submission for elemental analysis and SQUID measurements. Found: C, 47.05; $\mathrm{H}, 4.55 ; \mathrm{N}, 15.71 \%$. Calculated for $\left\{\mathrm{K}\left[\mathrm{Tb}(\text { tmphen })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right\} \cdot \mathrm{H}_{2} \mathrm{O} \cdot$ MeCN: C, 46.89; H, 4.22; N, 15.62\%.
$\left\{\mathrm{K}\left[\mathrm{Dy}(\text { tmphen })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right\}(3)-48 \mathrm{mg}$ tmphen $(0.2 \mathrm{mmol})$ and 38 mg $\mathrm{DyCl}_{3}$ ( 0.1 mmol , anhydrous basis) were dissolved in a mixture of $4 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}, 4 \mathrm{~mL}$ DMF, and 2 mL MeCN . This solution was added dropwise to a solution of $50 \mathrm{mg}(0.1 \mathrm{mmol})$ sample of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\text {III }}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ dissolved in $4 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}$ and 4 mL DMF. The yellow solution of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ gradually turned orange over the course of the addition. After being left to stand overnight, X-ray quality dark, orange crystals were harvested by filtration and washed with DMF and $\mathrm{Et}_{2} \mathrm{O}, 46 \mathrm{mg}, 23 \%$ yield. Samples were dried under vacuum prior to submission for elemental analysis and SQUID measurements. Found: C,
46.88; H, 4.89; N, $15.26 \%$. Calculated for $\left\{\mathrm{K}\left[\mathrm{Dy}(\operatorname{tmphen})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right\} \cdot \mathrm{H}_{2} \mathrm{O} \cdot$ DMF: C, 46.73; H, 4.20; N, 15.57\%.
$\left\{\mathrm{K}\left[\mathrm{Ho}(\text { tmphen })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right\}(4)-48 \mathrm{mg}$ tmphen $(0.2 \mathrm{mmol})$ and 38 mg $\mathrm{HoCl}_{3}$ ( 0.2 mmol , anhydrous basis) were dissolved in a mixture of $4 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}, 4 \mathrm{~mL}$ DMF, and 2 mL MeCN. This solution was added dropwise to a solution of $50 \mathrm{mg}(0.1 \mathrm{mmol})$ sample of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ dissolved in $4 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}$ and 4 mL DMF. The yellow solution of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ gradually turned orange over the course of the addition. After being left to stand overnight, X-ray quality dark, orange crystals were harvested by filtration and washed with DMF and $\mathrm{Et}_{2} \mathrm{O}, 40 \mathrm{mg}, 20 \%$ yield. Samples were dried under vacuum prior to submission for elemental analysis and SQUID measurements. Found: C, 49.45; H, 4.67; N, 14.00\%. Calculated for $\left\{\mathrm{K}\left[\mathrm{Ho}(\operatorname{tmphen})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right\} \cdot 2 \mathrm{Et}_{2} \mathrm{O}$ : C, 49.56; H, 4.96; N, 13.53\%.
$\left\{\mathrm{K}\left[\operatorname{Er}(\mathrm{tmphen})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right\}(5)-48 \mathrm{mg}$ tmphen $(0.2 \mathrm{mmol})$ and 38 mg $\mathrm{ErCl}_{3}$ ( 0.1 mmol , anhydrous basis) were dissolved in a mixture of $4 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}, 4 \mathrm{~mL}$ DMF, and 2 mL MeCN . This solution was added dropwise to a solution of $50 \mathrm{mg}(0.1 \mathrm{mmol})$ sample of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\text {III }}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ dissolved in $4 \mathrm{~mL} \mathrm{H} \mathrm{H}_{2} \mathrm{O}$ and 4 mL DMF. The yellow solution of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ gradually turned orange over the course of the addition. After being left to stand overnight, X-ray quality dark, orange crystals were harvested by filtration and washed with DMF and $\mathrm{Et}_{2} \mathrm{O}, 45 \mathrm{mg}, 22 \%$ yield. Samples were dried under vacuum prior to submission for elemental analysis and SQUID measurements. Found: C, 50.43; H, 4.32; N, 12.94\%. Calculated for $\left\{\mathrm{K}\left[\operatorname{Er}(\operatorname{tmphen})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right\} \cdot 2 \mathrm{Et}_{2} \mathrm{O}$ : C, 49.46; H, 4.95; N, 13.5\%.

## Infrared Spectroscopy

Infrared spectra were collected on a Nicolet 740 Fourier transform IR spectrometer. Samples were prepared and measured as a $\mathrm{Nujol}^{\circledR}$ mulls between KBr plates.

Figure 14. IR spectrum for 1. The peaks at 2098 and 2048 are typical for bridging and terminal cyanide ligands, respectively. The features from 1700-1500 are attributed to the aromatic tmphen ligands.

Figure 15. IR spectrum for 2. The peaks at 2110 and 2046 are typical for bridging and terminal cyanide ligands, respectively. The features from 1700-1500 are attributed to the aromatic tmphen ligands.

Figure 16. IR spectrum for 3. The peaks from 2120-2033 are typical for bridging and terminal cyanide ligands, respectively. The features from 1700-1500 are attributed to the aromatic tmphen ligands.

Figure 17. IR spectrum for 4. The peaks at 2098 and 2048 are typical for bridging and terminal cyanide ligands, respectively. The features from 1700-1500 are attributed to the aromatic tmphen ligands.

Figure 18. IR spectrum for 5. The peaks at 2109 and 2097 are typical for bridging and terminal cyanide ligands, respectively. The features from 1700-1500 are attributed to the aromatic tmphen ligands.

## Crystallography

Single crystals of the Ln-Mo chains were selected under Paratone ${ }^{\circledR}$ oil with a MiTGen microloop. Reflection data were collected on a Bruker D8-VENTURE diffractometer equipped with a $\mathrm{I} \mu \mathrm{S} \mathrm{Cu}$ microsource $(\lambda=1.54178 \AA$ ) and under a stream of $\mathrm{N}_{2}$ gas a 100 K . The frames were integrated and a semi-empirical absorption correction was applied using SADABS ${ }^{68}$ within the software package included in the APEX3 software suite. ${ }^{69}$ The structure was solved using SHELXT ${ }^{70}$ and refined using SHELXL; $;^{71}$ OLEX2 was used as an interface for the solution and refinement. ${ }^{72}$ Small Q-peaks in the structure that were consistent with the behavior of disordered solvent were removed using the SQUEEZE routine of the PLATON software package. ${ }^{73}$ Hydrogen atoms were placed in calculated positions.

The structures all contain a highly disordered $\left[\mathrm{Mo}(\mathrm{CN})_{7}\right]^{4-}$ moiety. Several methods of modeling were attempted; the $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment fit best with the data. When $\left\{\operatorname{Mo}(\mathrm{CN})_{6}\right\}$ was used instead, both the geometry and areas of electron density around the Mo centers suggested that some cyanide ligands were unaccounted for. The geometry of the Mo center is significantly distorted from pentagonal bipyramidal. The geometry is between that of a pentagonal bipyramid and a capped trigonal prism. The lanthanide ions have the geometry of a flattened square antiprism. The vertices of the two square faces in the antiprism are occupied by two nitrogen atoms from the tmphen ligand, one nitrogen atom from the cyanide ligand, and one oxygen atom from the water ligand. As mentioned above, the two square faces are closer together than in a perfect square antiprism, giving the geometry a "squashed" appearance. While the structures all
crystallized with identical unit cells, the refinements have some variation based on what fit best with each data set.

GdMo - The $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment is disordered in a 81:19 ratio. The Mo-C bond lengths for the major component ranged from $2.15(3) \AA$ to $2.406(19) \AA$. The Mo-C bond lengths in the minor component ranged from 2.13(2) $\AA$ to $2.43(2) \AA$. The Gd-N bonds from tmphen are $2.548(4) \AA$ and $2.543(4) \AA$, while the bond lengths of the Gd-N from cyanide and Gd-O are $2.71(5) \AA$ and $2.369(4) \AA$, respectively. Selected bond angles around the lanthanide centers are described in Table 6. The SADI restraint was used to restrain the cyanide bond lengths to each other. This was necessary to maintain the stability of the $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment - the lack of this restraint led to chemically unreasonable refinement results. The SIMU restraint was similarly used to model the thermal parameters on the $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragments; even with this restraint, the ISOR was needed to obtain a reasonable thermal parameter for nitrogen atom N8B. Additional details can be found in Table 1.

${ }^{\text {a }}$ Goodness-of-fit $=\left\{\Sigma\left[\mathrm{w}\left(\mathrm{Fo}^{2}-\mathrm{Fc}^{2}\right)^{2}\right] /(\mathrm{n}-\mathrm{p})\right\}^{1 / 2}$, where n is the number of reflections and p is the total number of parameters refined.
${ }^{\mathrm{b}} \mathrm{R}=\Sigma\|\mathrm{Fo}|-|\mathrm{Fc} \| / \Sigma| \mathrm{Fo}|$
$\left.\left.{ }^{\mathrm{c}} w \mathrm{R}=\left\{\Sigma\left[w\left(\mathrm{Fo}^{2}-\mathrm{Fc}^{2}\right)^{2}\right] / \Sigma w\left(\mathrm{Fo}^{2}\right)^{2}\right]\right\}\right\}^{1 / 2}$

Figure 19. Repeating unit of $\mathbf{1}$. Only the major component of the $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment is shown. Hydrogen atoms are omitted for clarity. Ellipsoids drawn at the $50 \%$ probability level.

2 - The $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment is disordered in a $82: 18$ ratio. The Mo-C bond lengths for the major component range from $2.237(10) \AA$ to $2.256(10) \AA$. The Mo-C bond lengths in the minor component range from $2.242(10) \AA$ A to $2.267(18) \AA$. The Tb-N bonds from tmphen are $2.532(5) \AA$ and $2.548(6) \AA$, while the bond lengths of the $\mathrm{Tb}-\mathrm{N}$ from cyanide and Tb-O are $2.76(5) \AA$ and $2.366(5) \AA$, respectively. Selected bond angles around the lanthanide centers are described in Table 6. SADI restraints were used on the cyanide bond lengths as well as the Mo-C bond lengths in the $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment. SIMU restraints were used on the thermal parameters of the atoms in the $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment. The ISOR restraint was again used on N8B, which was necessary to prevent a non-positive definite anisotropic thermal parameter. The constraints EXYZ and EADP were used on

N9A and N9B, as they were very close together and having a negative impact on the refinement when allowed to refine without those constraints. A SAME restraint was also used to restrain the geometries of the two $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragments with respect to each other. Additional details can be found in Table 2.

3 - The $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment is disordered in a 72.4:25.6 ratio. The Mo-C bond lengths for the major component range from $2.200(8) \AA$ to $2.221(9) \AA$. The Mo-C bond lengths in the minor component range from 2.205(9) $\AA$ to $2.223(9) \AA$. The Dy-N bonds from tmphen are 2.524(4) $\AA$ and $2.527(4) \AA$, while the bond lengths of the Dy-N from cyanide and Dy-O are $2.62(3) \AA$ and $2.317(4) \AA$, respectively. A similar list of restraints was used on $\mathbf{3}$ as with 2. Selected bond angles around the lanthanide centers are described in Table 6. There are SADI and restraints for the cyanide and Mo-C bond lengths, a SIMU and SAME restraint for the $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment, and one ISOR restraint for N8B. In addition, EXYZ and EADP were used for N9A and N9B. Additional details can be found in Table 3.

4 - The $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment is disordered in a 84.8:15.2 ratio. The Mo-C bond lengths for the major component range from $2.14(3) \AA$ to $2.26(3) \AA$. The Mo-C bond lengths in the minor component range from $2.11(4) \AA$ to $2.31(2) \AA$. The Ho-N bonds from tmphen are $2.507(3) \AA$ and $2.513(3) \AA$, while the bond lengths of the Ho-N from cyanide and Ho-O are 2.62(6) $\AA$ and $2.324(3) \AA$, respectively. Selected bond angles around the lanthanide centers are described in Table 6. A similar list of restraints was used on 4 as with 1-3. There are SADI and restraints for the cyanide, a SIMU and SAME restraint for the $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment, and one ISOR restraint for N8B. In addition, EXYZ and EADP were used for N9A and N9B. Additional details can be found in Table 4.

Figure 22. Asymmetric unit of 4. Only the major component of the $\left\{\operatorname{Mo}(\mathrm{CN})_{7}\right\}$ fragment is shown. Hydrogen atoms are omitted for clarity. Ellipsoids drawn at the 50\% probability level.

## Magnetic measurements

Measurements were performed on a Quantum Design MPMS-XL SQUID magnetometer equipped with a 7 T magnet. A polypropylene bag was used to secure the sample, and the diamagnetic contribution was subtracted from the raw data. Diamagnetic contributions from the sample were accounted for by using Pascal's constants. ${ }^{74}$

1 - Variable temperature static DC magnetic susceptibility measurements were performed on crushed crystals of $\mathbf{1}$ from 300 to 2 K under an applied field of 1000 Oe (Figure 24). The room temperature value of $8.5 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}$ is consistent with one Gd center and one $\mathrm{S}=1 / 2 \mathrm{Mo}^{\text {III }}$ center. The decrease, which accelerates as the sample is cooled to about 10 K , can be attributed to weak antiferromagnetic coupling between Gd and Mo , interchain interactions, or spin-orbit coupling. The reduced magnetization plot for $\mathbf{1}$ (Figure 25) shows that there is a small amount of anisotropy in the system, with near overlap of some isofield lines. This anisotropy likely originates from the spin-orbit coupling of $\mathrm{Mo}^{\text {III }}$. Since there is evidence of magnetic coupling between the metal centers and the reduced magnetization indicates spin-orbit coupling, it is possible that there is minor anisotropic exchange in the system. Alternating current (AC) measurements were performed to evaluate the magnetic dynamics of $\mathbf{1}$ (Figure 26). There was no notable slow relaxation of the magnetization observed, including in measurements that included a static DC field up to 2000 Oe. The lack of signal in these measurements indicates there is no SCM behavior in this chain.

Figure 24. Magnetic susceptibility data of 1.

Figure 25. Reduced magnetization plot for $\mathbf{1}$ with applied fields of 1-7 T in the $2-4 \mathrm{~K}$ range.

Figure 26. In-phase and out-of-phase susceptibility data for 1, measured at 2 K with applied static DC fields from 0-2000 Oe.

2 - Variable temperature static DC magnetic susceptibility measurements were performed on crushed crystals of $\mathbf{2}$ from 300 to 2 K under an applied field of 1000 Oe (Figure 27). The room temperature value of $11.3 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}$ is consistent with one Tb center and one $\mathrm{S}=1 / 2 \mathrm{Mo}^{\text {III }}$ center. The sharp decrease near 2 K is likely due to interchain interactions, though it is possible that there is also weak coupling between Mo and Tb . The reduced magnetization plot for 2 (Figure 28) does not have superimposed isofield lines, which indicates that there is magnetic anisotropy in the system. The anisotropy present is likely a combination of exchange anisotropy and single-ion anisotropy from Tb , as well as spin-orbit coupling from $\mathrm{Mo}^{\text {III }}$. Alternating current (AC) measurements were performed to evaluate the magnetic dynamics of 2 (Figure 29). A weak signal was observed in $\chi^{\prime \prime}$, which indicates that there was some slow relaxation of the magnetization, but not at a level expected for SCM behavior.

Figure 27. Magnetic susceptibility data of 2.

Figure 28. Reduced magnetization plot for $\mathbf{2}$ with applied fields of 1-7 T in the $2-4 \mathrm{~K}$ range.

Figure 29. In-phase and out-of-phase susceptibility data for 2, measured at 2 K with applied static DC fields from 0-2000 Oe.

3 - Variable temperature static DC magnetic susceptibility measurements were performed on crushed crystals of $\mathbf{3}$ from 300 to 2 K under an applied field of 1000 Oe (Figure 30). The room temperature value of $14.0 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}$ is consistent with one Dy center and one $S=1 / 2 \mathrm{Mo}^{\text {III }}$ center. The decrease at low temperature can be attributed to antiferromagnetic coupling between Dy and Mo or interchain interactions, including the sharp increase near 4 K . The reduced magnetization plot for $\mathbf{3}$ (Figure 31) does not have superimposed isofield lines, which shows that there is magnetic anisotropy in the system. The anisotropy present is likely a combination of exchange anisotropy and single-ion anisotropy from Dy, as well as spin-orbit coupling from $\mathrm{Mo}^{\mathrm{III}}$. Alternating current (AC) measurements were performed to evaluate the magnetic dynamics of $\mathbf{3}$ (Figure 32). The beginnings of an out-of-phase signal are be observed, but the frequency limitations of the instrument prevent the peaks from being visible under these conditions. $\mathbf{3}$ may have some weak magnetic memory behavior under an applied field, but it is not possible to quantify that behavior without the peaks in the data.

Figure 30. Magnetic susceptibility data of 3.

Figure 31. Reduced magnetization plot for $\mathbf{3}$ with applied fields of 1-7 T in the $2-4 \mathrm{~K}$ range.

Figure 32. In-phase and out-of-phase susceptibility data for $\mathbf{3}$, measured at 2 K with applied static DC fields from 0-2000 Oe.

4 - Variable temperature static DC magnetic susceptibility measurements were performed on crushed crystals of 4 from 300 to 2 K under an applied field of 1000 Oe (Figure 33). The room temperature value of $12.8 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}$ is close to the expectated spin-only value for one Ho center and one $S=1 / 2 \mathrm{Mo}^{\text {III }}$ center $\left(13.9 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}\right)$. The decrease at low temperature can be attributed to antiferromagnetic coupling between Ho and Mo or interchain interactions. The reduced magnetization plot for 4 (Figure 34) does not have superimposed isofield lines, which indicates the presence of magnetic anisotropy in the system. The anisotropy present is likely a combination of exchange anisotropy and single-ion anisotropy from Ho, as well as spin-orbit coupling from $\mathrm{Mo}^{\text {III }}$. Alternating current (AC) measurements were performed to evaluate the magnetic dynamics of 4 (Figure 35). An out-of-phase signal is not observed for 4, despite the observation of magnetic anisotropy.

Figure 33. Magnetic susceptibility data of 4.

Figure 34. Reduced magnetization plot for 4 with applied fields of 1-7 T in the 2-4 K range.

Figure 35. In-phase and out-of-phase susceptibility data for 4 , measured at 2 K with applied static DC fields from 0-2000 Oe.

5 - Variable temperature static DC magnetic susceptibility measurements were performed on crushed crystals of $\mathbf{5}$ from 300 to 2 K under an applied field of 1000 Oe (Figure 36). The room temperature value of $12.1 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}$ is consistent with expectations for one Er center and one $\mathrm{S}=1 / 2 \mathrm{Mo}^{\text {III }}$ center $\left(11.8 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}\right)$. The decrease at low temperature can be attributed to coupling between Er and Mo or interchain interactions. The reduced magnetization plot for 5 (Figure 37) does not have superimposed isofield lines, which shows that there is magnetic anisotropy in the system, although less anisotropy than was observed for $\mathbf{3}$ and 4. The anisotropy present is likely a combination of exchange anisotropy and single-ion anisotropy from Er, as well as spin-orbit coupling from $\mathrm{Mo}^{\text {III }}$. Alternating current (AC) measurements were performed to evaluate the magnetic dynamics of $\mathbf{5}$ (Figure 38). Like $\mathbf{4}, \mathbf{5}$ shows the beginnings of an out-of-phase signal, but it is likewise difficult to quantify the response due to frequency limitations of the SQUID instrument.

The existence of a small amount of anisotropic exchange in these compounds is evident due to the anisotropy present in $\mathbf{1}$, but the small amount of anisotropy is insufficient to induce SCM behavior. In the other compounds in the series, if there is anisotropic exchange, it would likely have competing axes with single-ion sources of anisotropy on the lanthanide ions. It is possible that inducing stronger coupling to an orbitally degenerate metal center could lead to anisotropic exchange coupled SMMs or SCMs, but the weak coupling through cyanide is insufficient to induce that change.

Figure 36. Magnetic susceptibility data of 5.

Figure 37. Reduced magnetization plot for $\mathbf{5}$ with applied fields of 1-7 T in the $2-4 \mathrm{~K}$ range.

Figure 38. In-phase and out-of-phase susceptibility data for 5 , measured at 2 K with applied static DC fields from 0-2000 Oe.

## Conclusions and Future Studies

A family of cyanide bridge $\mathrm{Ln}^{\text {III }}-\mathrm{Mo}{ }^{\text {III }}$ atoms were synthesized and characterized structurally and magnetic measurements. The inclusion of a 7 -coordinate $\mathrm{Mo}^{\mathrm{III}}$ center in a chain with a lanthanide ion is novel, but did not lead to SCM behavior in this case. In future studies, other bridging ligands could be used to try to increase the amount of coupling between the lanthanide ion and the molybdenum center. Like in other cases that show anisotropic exchange, the best strategy would likely be strongly coupled $\mathrm{Mo}^{\mathrm{III}}$ to $\mathrm{Gd}^{\text {III }}$, because there would be no single-ion anisotropy from $\mathrm{Gd}^{\text {III }}$ to interfere with the anisotropy from superexchange. In order to increase coupling, a different bridging ligand should be employed. Diamagnetic bridging ligands are known to provide limited coupling between transition metals and lanthanides due to the contracted f-orbitals on lanthanide centers. If a radical bridging ligand was used, it is possible that the coupling would be increased and better magnetic properties could be expected.

## CHAPTER III

# PREPARATION AND REACTIONS OF SEVEN COORDINATE MOLYBDENUM(III) COMPOUNDS* 

## Background

The discovery of magnetic bistability for $\mathrm{Mn}_{12}$ acetate ${ }^{1}$ in 1993 opened the door to wide exploration of magnetic behavior in molecular materials. Cyanide compounds experienced a renaissance in this area owing to the discovery of fascinating magnetic properties in Prussian Blue analogues such as the material $\mathrm{V}^{\mathrm{II}}\left[\mathrm{Cr}^{\mathrm{II}}(\mathrm{CN})_{6}\right]_{0.86} \cdot 2.8 \mathrm{H}_{2} \mathrm{O}$, which exhibits magnetic ordering above room temperature. ${ }^{23}$ Over the past twenty years, hexacyanometallates, octacyanometallates, as well as heteroleptic cyanide precursors have been studied extensively vis-à-vis their capacity to be incorporated into extended networks as well as discrete molecules. ${ }^{33,75-76}$ In the latter category, single molecule magnets (SMMs) prepared from cyanometallate building blocks are especially intriguing due to their potential applicability to quantum computing, data storage, and spintronics. ${ }^{9,11,22,77}$ SMMs function as nanomagnets with a thermal energy barrier to reversal of their magnetization. Even in cases with record coupling ${ }^{78-79}$ and large ground state spin values, ${ }^{16}$ however, SMM behavior is still relatively elusive in cyanide-bridged materials. Investigating

[^0]underexplored geometries and architectures can aid in the understanding of including how to improve their magnetic properties.

Molecular wheels are well-known in the magnetism and coordination chemistry communities, with many different bridging ligands having been used to obtain cyclic architectures. Among these wheels are examples that contain lanthanides and transition metals with a wide variety of bridging ligands including azides, carboxylates, polyolates, polyamines, oxides, polyols, and hydroxides. ${ }^{80-88}$ Wheel examples with cyanide, however, are rather limited, ${ }^{16,89-94}$ despite the interesting magnetic phenomena observed for some of those compounds. One of these molecules, $\left[\mathrm{Mn}^{\mathrm{III}}(\text { salen })\right]_{6}\left[\mathrm{Fe}^{\mathrm{III}}(\mathrm{bpmb})(\mathrm{CN})_{2}\right]_{6} \cdot 7 \mathrm{H}_{2} \mathrm{O}$ exhibits magnetic hysteresis consistent with SMM behavior. ${ }^{90}$ Another interesting molecule reported by the Dunbar group, namely $\left[\mathrm{Mn}(\text { dpop })\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]_{2}\left[\left\{\mathrm{Mo}(\mathrm{CN})_{7}\right\}_{8}\{\mathrm{Mn}(\text { dpop })\}_{10}\left\{\mathrm{Mn}(\text { dpop })\left(\mathrm{H}_{2} \mathrm{O}\right)\right\}_{4}\right] \cdot \mathrm{xH}_{2} \mathrm{O}($ dpop $=2,13-$ dimethyl-3,6,9,12,18-pentaazabicyclo-[12.3.1]octadeca-1(18),2,12,14,16-pentaene), has the largest spin ground state for a cyanide bridged molecule. ${ }^{16}$ Based on that result and the dearth of cyanide-bridged wheels, pursuit of other wheel architectures utilizing $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ as a building block is warranted.

The $S=1 / 2$ anion $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ has attracted interest in the area of cyanide magnetism due to its five-fold symmetry and atypical coordination geometries in magnetic systems. Early studies by Kahn and coworkers focused on the incorporation of $\left[\mathrm{Mo}(\mathrm{CN})_{7}\right]^{4-}$ into extended cyanide-bridged networks. The seven-coordinate geometry precludes the formation of the highly symmetric networks typically observed for hexaand octacyanometallates and leads to increased magnetic anisotropy. ${ }^{55,57}$ Examples of
molecules containing the $\left[\mathrm{Mo}^{\text {III }}(\mathrm{CN})_{7}\right]^{4-}$ moiety are scarce, however; results from our laboratories have provided the only examples that satisfy the conditions for SMMs, viz. the $\mathrm{Mo}^{\text {III }}$ center having pseudo- $\mathrm{D}_{5 \mathrm{~h}}$ geometry and a 3 d metal being coordinated to the apical cyanide ligands which maximizes Ising anisitropy. ${ }^{28,38-39,95}$ While one would not expect to preserve the $\mathrm{D}_{5 \mathrm{~h}}$ symmetry when incorporating $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ into wheel architectures, isolation of new cyclic molecules with this anion allows for more data to be added to the scarce information about the magnetism of this building block. One family of wheels that incorporates homoleptic cyanometallates have the formula $\left[\mathrm{M}^{\mathrm{IV}}(\mathrm{CN})_{8}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}(\mathrm{M}=\mathrm{Nb}, \mathrm{Mo}$, or W$)$. Weak antiferromagnetic interactions between the Ni centers in $\left[\mathrm{Mo}^{\mathrm{IV}}(\mathrm{CN})_{8}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{92}$ and antiferromagnetic interactions between Nb and Ni in $\left[\mathrm{Nb}^{\mathrm{IV}}(\mathrm{CN})_{8}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}$ were reported in the original publications. ${ }^{94}$ The magnetic properties of $\left[W^{\mathrm{IV}}(\mathrm{CN})_{8}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}$ were not reported. ${ }^{93}$

In this report, the synthesis of the $\mathrm{Mo}^{\text {III }}$ analogue $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}(7)$ is shown to be possible by emulating reaction conditions used to prepare $\left[\mathrm{Mo}^{\mathrm{IV}}(\mathrm{CN})_{8}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}(\mathbf{8})$. The $\mathrm{Mo}^{\mathrm{IV}}$ analogue, 8 was also re-synthesized and measured to directly compare data for the two molecules. A new, simpler procedure for the synthesis of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}(6)^{96}$ was also developed. Characterizing the new wheel compound reignited interest in syntheses that might yield proper geometries for anisotropic exchange with $\mathrm{Mo}^{\mathrm{III}}$. As previously stated, the $\mathrm{D}_{5 \mathrm{~h}}$ geometry is critical to the observation of Ising-type anisotropic exchange. Rather than using $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ as a building block and hoping to preserve its pentagonal bipyramidal geometry, it would
significantly aid the efforts to make polynuclear SMMs if a starting material existed that would naturally enforce such a geometry. With that goal in mind, $\mathrm{Mo}^{\mathrm{III}} \mathrm{Cl}_{3}(\mathrm{THF})_{3}$ was reacted with the organic Schiff base ligand DAPB ( $(2 E, 12 E)$-2,13-dimethyl-6,9-dioxa-3,12-diaza-1(2,6)-pyridinacyclotridecaphane-2,12-diene). ${ }^{97-98}$ The reaction led to the isolation of the product $\left[\mathrm{Mo}^{\text {III }} \mathrm{DAPB}(\mathrm{CN})_{2}\right]^{-}$, which is an exciting new building block that optimizes the geometry of the orbitally degenerate $\mathrm{Mo}^{\text {III }}$ center, satisfying the conditions for anisotropic exchange. DAPB has been used in a similar fashion before, but not with an orbitally degenerate metal center. ${ }^{99}$ Using a similar strategy with $\mathrm{Mo}^{\text {III }}$ should enable new complexes to be prepared that exhibit Ising-type anisotropic exchange.

## Experimental Details

## Synthesis

Syntheses were carried out under air free conditions using a nitrogen-filled glove box or Schlenk-line outfitted with argon gas. The solvents were deoxygenated by sparging with argon gas and the dry EtOH was dried over Mg and $\mathrm{I}_{2}$. Diethyl ether was purified using an MBRAUN purification system. $\mathrm{Mo}^{\mathrm{III}} \mathrm{Cl}_{3}(\mathrm{THF})_{3}, \mathrm{Ni}(\mathrm{L})\left(\mathrm{ClO}_{4}\right)_{2}$, and DAPB were prepared by literature methods ${ }^{97-98,100-101}$; all other chemicals were purchased from commercial sources and used without further purification unless otherwise indicated.

## $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot \mathbf{2 H} \mathbf{H}_{2} \mathrm{O}(6)$

A $3.2 \mathrm{~g}(7.64 \mathrm{mmol})$ sample of $\mathrm{Mo}^{\mathrm{III}} \mathrm{Cl}_{3}(\mathrm{THF})_{3}$ and $4.4 \mathrm{~g}(66.9 \mathrm{mmol})$ of KCN were added to a flask containing 40 mL of $\mathrm{H}_{2} \mathrm{O}$ and heated to $70^{\circ} \mathrm{C}$ for 12 h to yield a dark
orange solution. MeOH was subsequently added until the solution became slightly cloudy. After left to stand overnight at $25^{\circ} \mathrm{C}$, X-ray quality dark olive-green crystals were isolated ( $2.48 \mathrm{~g}, 69 \%$ yield). IR ( $v$ for $\mathrm{C} \equiv \mathrm{N}$ ): $2115 \mathrm{sh}, 2101 \mathrm{~s}, 2067 \mathrm{vs} \mathrm{cm}^{-1}$.

## $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12} \cdot \mathbf{2 4 H} \mathrm{H}_{2} \mathrm{O}$ (7)

A $25 \mathrm{mg}(0.05 \mathrm{mmol})$ sample of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ was dissolved in 6 mL of $\mathrm{H}_{2} \mathrm{O}$. A separate sample ( $25 \mathrm{mg}, 0.05 \mathrm{mmol}$ ) of $\mathrm{Ni}(\mathrm{L})$ was dissolved in 6 mL of $\mathrm{H}_{2} \mathrm{O}$ and added dropwise to the solution of $\mathrm{K} 4\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$. After standing overnight, the dark orange needle crystals were collected by filtration and washed with $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{Et}_{2} \mathrm{O}$, $27 \mathrm{mg}, 50 \%$ yield. Samples were dried under vacuum prior to submission for elemental analysis and SQUID measurements. Found: C, 44.94; N, 21.34; H, 5.17\%. Calc. for $\left[\mathrm{Mo}^{\text {III }}(\mathrm{CN})_{7}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12} \cdot 24 \mathrm{H}_{2} \mathrm{O}: \mathrm{C}, 45.15 ; \mathrm{N}, 21.35 ; \mathrm{H}, 5.33 \%$. IR ( $v$ for $\mathrm{C} \equiv \mathrm{N}$ ): 2090 m , $2077 \mathrm{~m}, 2042 \mathrm{sh}, 2033 \mathrm{~m} \mathrm{~cm}^{-1}$.

## $\left[\mathrm{Mo}^{\mathrm{IV}}(\mathrm{CN})_{8}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12} \cdot \mathbf{3 0 H}_{2} \mathrm{O}(8)$

A 65 mg sample of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{IV}}(\mathrm{CN})_{8}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ was dissolved in 8 mL of $\mathrm{H}_{2} \mathrm{O}$. A separate 50 mg sample of $\mathrm{Ni}(\mathrm{L})$ was dissolved in 8 mL of $\mathrm{H}_{2} \mathrm{O}$ and added dropwise to the solution of $\mathrm{K}_{4}\left[\mathrm{Mo}^{\mathrm{IV}}(\mathrm{CN})_{8}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$. After standing overnight, dark yellow needle crystals were collected by filtration and washed with $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{Et}_{2} \mathrm{O}, 34 \mathrm{mg}, 32 \%$ yield. The sample was dried under vacuum prior to submission for elemental analysis and SQUID measurements. Found: C, 44.40; N, 21.74; H, 5.22\%. Calc for
$\left[\mathrm{Mo}^{\mathrm{IV}}(\mathrm{CN})_{8}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12} \cdot 30 \mathrm{H}_{2} \mathrm{O}: \mathrm{C}, 44.39 ; \mathrm{N}, 21.79 ; \mathrm{H}, 5.29 \%$. IR ( $v$ for $\mathrm{C} \equiv \mathrm{N}$ ): 2150sh, 2144m, 2131m, 2119w, 2100s, 1626m, $1579 \mathrm{~m} \mathrm{~cm}^{-1}$.

## $\mathbf{M o}^{\text {IV }} \mathrm{DAPBCl}_{2}$ (9)

A 1.0 g sample $(2.12 \mathrm{mmol})$ of $\mathrm{MoCl}_{3}(\mathrm{THF})_{3}$ and an 850 mg sample $(2.12 \mathrm{mmol})$ of $\mathrm{DAPBH}_{2}$ were added to a Schlenk fask with 50 mL MeCN . After refluxing for about 2 hours, a black, crystalline powder was observed in the flask. It was left to stir for another hour and the X-ray quality crystals were filtered in air and washed with $\mathrm{MeCN}, 1.0 \mathrm{~g}, 83 \%$ yield.

## $\left(\mathrm{NEt}_{4}\right)\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{DAPB})(\mathrm{CN})_{2}\right](10)$

A $2.72 \mathrm{~g}(0.48 \mathrm{mmol})$ sample of $\mathrm{Mo}^{\mathrm{IV}}(\mathrm{DAPB}) \mathrm{Cl}_{2}$ was placed in a Schlenk flask with a $225 \mathrm{mg}(1.44 \mathrm{mmol})$ sample of $\left(\mathrm{NEt}_{4}\right) \mathrm{CN}$ and 20 mL MeCN . The mixture was subjected to reflux for 12 hours, after which there was a green solution and some dark particulate matter. The solution was filtered to separate the filtrate and the solid. After slow diffusion of $\mathrm{Et}_{2} \mathrm{O}$ into the filtrate, a small number of X-ray quality, dark green crystals were observed.

## $\mathbf{K}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{DAPB})(\mathrm{CN})_{2}\right](11)$

A $100 \mathrm{mg}(0.177 \mathrm{mmol})$ sample of $\mathrm{Mo}^{\mathrm{IV}} \mathrm{DAPBCl}_{2}$ was placed in a Schlenk flask with $23 \mathrm{mg}(0.354 \mathrm{mmol}) \mathrm{KCN}$ and 30 mL of dry ethanol. The mixture was refluxed for 12 hours, which resulted in a yellow solution with brown solid. After filtration, the filtrate
was subjected to slow diffusion with $\mathrm{Et}_{2} \mathrm{O}$ and Xray quality, dark brown crystals were isolated, $13 \mathrm{mg}, 12.5 \%$ yield.

## Crystallography

Single crystals of each complex were selected under Paratone ${ }^{\circledR}$ oil with a MiTGen microloop. Reflection data were collected on a Bruker D8-VENTURE diffractometer equipped with a $\mathrm{I} \mu \mathrm{S} \mathrm{Cu}$ microsource $(\lambda=1.54178 \AA$ ) or a Bruker D8-QUEST diffractometer equipped with a $\mathrm{I} \mu \mathrm{S}$ Mo microsource $(\lambda=0.71073 \AA$ ) under a stream of N2 gas a 100 K . The frames were integrated and a semi-empirical absorption correction was applied using SADABS ${ }^{68}$ within the software package included in the APEX3 software suite. ${ }^{69}$ The structure was solved using SHELXT ${ }^{70}$ and refined using SHELXL; ;11 OLEX2 was used as an interface for the solution and refinement. ${ }^{72}$ Small Q-peaks in the structure that were consistent with the behavior of disordered solvent were removed using the SQUEEZE routine of the PLATON software package. ${ }^{73}$ Hydrogen atoms were placed in calculated positions.

## $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12} \cdot \mathbf{2 4 H}_{2} \mathrm{O}$ (7)

Compound 7 crystallizes in $\mathrm{P} \overline{1}$ with a unit cell that is metrically similar to that of $\mathbf{8}$ which crystallizes in $R \overline{3}$. The molecule of $\mathbf{7}$ resides on a crystallographic inversion center with one-half of the complex in the asymmetric unit (Figure 39). The structure consists of six $\left[\mathrm{Mo}^{\text {III }}(\mathrm{CN})_{7}\right]^{4-}$ moieties bridged to six $[\mathrm{Ni}(\mathrm{L})]$ moieties in an alternating arrangement to give a wheel motif. The remaining six $[\mathrm{Ni}(\mathrm{L})]^{2+}$ act as capping ligands for the wheel
with one coordinated water in the Ni axial position opposite the cyanide ligand. The coordination geometry around the $\mathrm{Mo}^{\text {III }}$ centers was evaluated using the SHAPE program, which calculates a continuous shape measurement (CShM) based on the positions of the atoms relative to their positions in ideal geometries (closer to 0 is a better match). ${ }^{102-103}$ The coordination geometries of the Mo centers are best described as capped trigonal prismatic. Mo3 is a particularly good fit for that geometry and the results of those calculations are compiled in Table 7. The angles between the equatorial cyanide ligands range from $71.9(4)^{\circ}$ to $76.4(3)^{\circ}$, which are close to the $72^{\circ}$ for a perfect pentagon. OLEX2 was used to calculate a mean plane of the equatorial cyanide ligands on each $\mathrm{Mo}^{\mathrm{III}}$ center in 7; the rmsd values for each of those planes are $0.549,0.535$, and 0.579 for Mo1-Mo3, further showing that the cyanide ligands are distorted compared to a perfect pentagonal arrangement. The $\mathrm{Ni}^{\mathrm{II}}$ centers all adopt an approximately octahedral geometry, with the four equatorial positions being occupied by the N atoms of L and the axial positions filled with either two cyanide ligands (for the Ni atoms in the ring), or one cyanide ligand and one water ligand (for the Ni atoms on the outside). Additional information regarding the structure can be found in Table 8.

Table 7. SHAPE results for crystallographically independent $\mathrm{Mo}^{\mathrm{III}}$ centers in 7.

## $\left[\mathrm{Mo}^{\mathrm{IV}}(\mathrm{CN})_{8}\right]_{6}[\mathrm{Ni}(\mathrm{L})]_{12} \cdot \mathbf{3 0 H}_{2} \mathrm{O}(8)$

The structure of $\mathbf{8}$ was previously reported by the Wang group in 2017. ${ }^{92}$ The structure was collected at room temperature, and for the sake of direct comparison to 7, it was re-collected at 110 K . The structure is superficially similar to 7 , and is reported in the rhombohedral setting to facilitate comparison of its unit cell to 7 (Table 9). The unit cell of this data is slightly smaller than the cell of the previously reported data, as might be expected from the lowered temperature. More details can be found in Table 10.

## $\mathbf{M o}^{\mathbf{I V}} \mathrm{DAPBCl}_{2}$ (9)

Compound 9 crystallizes in the space group $\mathrm{P} 2_{1} / \mathrm{C}$. The structure was previously reported by the Yagubskii group, ${ }^{104}$ and they noted that the structure is remarkably close to pentagonal bipyramidal. There are no anions in the structure; the ligand, $\mathrm{DAPBH}_{2}$, becomes deprotonated during the reaction, leading to the formation of a neutral compound. The bond lengths to the two $\mathrm{Cl}^{-}$ligands are $2.3868(14) \AA$ and $2.3912(14) \AA$. More details can be found in Table 11.

Figure 41. Crystal structure of 9. Ellipsoids are drawn at the 50\% probability level.

## $\left(\mathrm{NEt}_{4}\right)\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{DAPB})(\mathrm{CN})_{2}\right](10)$

10 crystallizes in the space group $\mathrm{Pna} 2{ }_{1}$. The geometry of the $\mathrm{Mo}^{\text {III }}$ center is still close to pentagonal bipyramidal, but the DABP ligand lies less flat than it does in 9 . The $\left[\mathrm{NEt}_{4}\right]^{+}$moiety is disordered and was able to be modeled in two positions. The Mo-C bonds to the cyanide ligands are $2.177(7) \AA$ and $2.172(6) \AA$, respectively. More information can be found in Table 12, and the structure is shown in Figure 42.

Figure 42. Crystal structure of 10. Only one configuration of the disordered $\left[\mathrm{NEt}_{4}\right]^{+}$is shown. Ellipsoids are drawn at the $50 \%$ probability level.

\end{aligned}
$$

## $\mathbf{K}\left[\mathrm{Mo}^{\text {III }}(\mathrm{DAPB})(\mathrm{CN})_{2}\right](11)$

Compound $\mathbf{1 1}$ crystallizes in the space group $\mathrm{P} 2_{1} / \mathrm{n}$. There are two $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{DAPB})\right]^{-}$ fragments in the unit cell. The geometry of the $\mathrm{Mo}^{\text {III }}$ centers is slightly distorted due to the presence of the $\mathrm{K}^{+}$ions, which bend the cyanide ligands away from the ideal geometry the angle between these ligands is $167.584^{\circ}$ and $167.060^{\circ}$ for the two complexes in the unit cell, respectively, which is a significant deviation from the ideal of $180^{\circ}$. The Mo-C bond lengths for these axial cyanide ligands are $2.16(2) \AA, 2.20(2) \AA, 2.20(2) \AA$, and 2.134(18) Å. There are large Q-peaks that appear to correspond to solvent molecules that act as ligands on $\mathrm{K}^{+}-$all efforts to model those peaks resulted in chemically unreasonable refinements. The difficulty in modelling those peaks is due to disorder of the ligands, whose likely identity is EtOH. Additional details can be found in Table 13. The structure is shown from two angles in Figure 43.

Table 14 contains some comparisons of the bond angles in $\mathbf{9}, \mathbf{1 0}$ and 11. Consistently, the O-Mo-O bond angle is the widest for the DAPB compounds, but their closeness to the perfect pentagonal angle of $72^{\circ}$ is noteworthy because of the dependence of the orbital degeneracy on the geometry of the metal center.

## Cyclic Voltammetry

Cyclic voltammetry was performed on 9 to evaluate its redox potential. Electrochemical measurements were carried out under an inert $\mathrm{N}_{2}$ atmosphere using dichloromethane that had been dried over molecular sieves, using $0.1 \mathrm{M}\left[\mathrm{n}-\mathrm{Bu}_{4} \mathrm{~N}\right]\left[\mathrm{PF}_{6}\right]$ as the supporting electrolyte. The setup used an HCH Electrochemical Analyzer model CH 1620 A with a glassy carbon working electrode, Pt wire auxiliary electrode, and a $\mathrm{Ag} / \mathrm{AgCl}$ ( $3 \mathrm{M} \mathrm{KCl}(\mathrm{aq})$ ) reference electrode at a $100 \mathrm{mV} / \mathrm{s}$ scan rate. The concentration of 9 was $\sim 100 \mathrm{mM}$. Ferrocene was used as an internal standard and exhibited an $\mathrm{E}_{1 / 2}=0.44 \mathrm{~V}$ vs $\mathrm{Ag} / \mathrm{AgCl}$ for the $\mathrm{Fc}+/ \mathrm{Fc}$ couple under the same experimental conditions. Data shown in Figure 44.

Figure 44. Cyclic voltammograms of 9 in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (DCM).

The cyclic voltammogram exhibits a reversible oxidation at 1.21 V and reversible reduction couples located at $\mathrm{E}_{1 / 2}=-0.239 \mathrm{~V}$ and $\mathrm{E}_{1 / 2}=-1.08 \mathrm{~V}$ for 9 . These results indicate that the $\mathrm{Mo}^{\mathrm{III}}$ analogue is accessible as well as the $\mathrm{Mo}^{\mathrm{V}}$ and $\mathrm{Mo}^{\text {II }}$ species.

## Magnetic Measurements

Magnetic measurements were performed on a Quantum Design MPMS-XL SQUID magnetometer equipped with a 7 T magnet. A polypropylene bag was used to secure the sample, and the diamagnetic contribution was subtracted from the raw data. Diamagnetic contributions from the sample were accounted for by using Pascal's constants. ${ }^{74}$

Variable temperature static DC magnetic susceptibility measurements were performed on crushed crystals of 7 from 300 to 2 K under an applied field of 1000 Oe (Figure 45). The room temperature $\chi_{m} \mathrm{~T}$ value of $19.07 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ is higher than the spinonly value of $14.25 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\left(\mathrm{~g}_{\mathrm{Mo}}=2.0, \mathrm{~S}_{\mathrm{Mo}}=1 / 2, \mathrm{~g}_{\mathrm{Ni}}=2.0, \mathrm{~S}_{\mathrm{Ni}}=1\right)$ for the $18-\mathrm{metal}$ center wheel. Calculations on seven-coordinate $\mathrm{Mo}^{\mathrm{III}}$ centers have revealed that, even in distorted geometries, the $g$-values are highly anisotropic, with $g_{z}$ ranging from 3.0 to 3.5 and $g_{x}=g_{y}$ ranging from $0.4-1.3 .{ }^{28}$ Calculations (vide infra) predict an average $g_{\text {iso }}$ value between 2.23-2.24 for the $\mathrm{Ni}^{\mathrm{II}}$ centers, which also has a substantial effect on $\chi_{m} \mathrm{~T}$. The observed room temperature $\chi_{m} \mathrm{~T}$ value is easily explained when accounting for these highly anisotropic $g$ values ( $19.10 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}, g_{\mathrm{Mo}}=1.80, \mathrm{~S}_{\mathrm{Mo}}=1 / 2, g_{\mathrm{Ni}}=2.40, \mathrm{~S}_{\mathrm{Ni}}=1$ ). The $\chi_{m} \mathrm{~T}$ value increases from $19.07 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ at 300 K to a maximum of $22.92 \mathrm{~cm}^{3} \mathrm{~mol}^{-}$ ${ }^{1} \mathrm{~K}$ at 5 K before dropping precipitously as the temperature is lowered to 2 K . The decrease
in $\chi_{m} \mathrm{~T}$ at very low temperatures is the result of zero-field splitting of the $\mathrm{Ni}^{\mathrm{II}}$ centers. The increase from 300 to 5 K is likely due to coupling between the $\mathrm{Ni}^{\mathrm{II}}$ and $\mathrm{Mo}^{\mathrm{III}}$ centers. In the case where one set of Ni-Mo couplings is ferromagnetic and another set is antiferromagnetic (this is possible when inner-ring six $\mathrm{Ni}^{\mathrm{II}}$ and all $\mathrm{Mo}^{\mathrm{III}}$ spins are parallel and the external six $\mathrm{Ni}^{\text {II }}$ centers are antiparallel), then $S=3$ would be expected; the room temperature value of $\chi_{m} \mathrm{~T}$ rules out such a possibility, since $\chi_{m} \mathrm{~T}$ would be expected to be $6 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ in that case. Both fully antiferromagnetic $\left(\mathrm{S}=9, \chi_{m} \mathrm{~T}=45 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right.$, when all the $\mathrm{Ni}^{\mathrm{II}}$ centers have a spin-up configuration and all the $\mathrm{Mo}^{\text {III }}$ have a spin-down configuration) and fully ferromagnetic $\left(\mathrm{S}=15, \chi_{m} \mathrm{~T}=120 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right.$, when all $\mathrm{Ni}^{\mathrm{II}}$ and $\mathrm{Mo}^{\text {III }}$ centers have a spin-up configuration) coupling would lead to an increase in $\chi_{m} \mathrm{~T}$ at low temperatures.

The magnetic susceptibility data for $\mathbf{8}$ reveal a value of $12.6 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ at 300 K , which is close to the previously reported value of $12.19 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ at $300 \mathrm{~K} .{ }^{92}$ The data for the magnetic susceptibility of $\mathbf{8}$ are included in Figure 45 to facilitate direct comparison of the magnetic properties, which clearly exhibit differences in magnetic behavior. The number of metal centers present in 7 precludes the use of complete models to fit the data - attempts based on previously reported methods ${ }^{\mathbf{1 0 5}}$ have not yielded satisfactory fits.

Figure 45. Magnetic susceptibility plots of 7 (black dots) and $\mathbf{8}$ (red dots).

The magnetization data and reduced magnetization data are instructive in further exploring the magnetic properties of 7 . The 1.8 K magnetization data for 7 (Figure 46) do not saturate up to a field of 7 T , at which field the magnetization is $21.8 \mu_{\mathrm{B}}$. The spin-only value predicted for an $\mathrm{S}=9$ ground state (antiferromagnetic coupling between $\mathrm{Ni}^{\mathrm{II}}$ and $\mathrm{Mo}^{\text {III }}$ ) is $18 \mu_{\mathrm{B}}$, whereas the value predicted for $\mathrm{S}=15$ (ferromagnetic coupling) is $30 \mu_{\mathrm{B}}$. While there is a lack of saturation, the expected value for antiferromagnetic coupling is already exceeded at 7 T , suggesting that the coupling is ferromagnetic. The reduced magnetization data (Figure 47) show that there is anisotropy in the system, even if it is not Ising-type anisotropy that would lead to SMM behavior. The lack of SMM behavior, even with applied DC fields, can be clearly seen in Figure 48.

## Infrared Spectroscopy

Infrared spectra were collected on a Nicolet 740 Fourier transform IR spectrometer. Samples were prepared and measured as a $\mathrm{Nujol}^{\circledR}$ mulls between KBr plates. The data clearly show a difference between 7 and 8 .

Figure 49. IR spectra for 7 and 8. Large peaks at 2900, 1460, and 1377 are from the Nujol ${ }^{\circledR}$ used in the mull. The lower spectrum is zoomed in on the cyanide stretching region.

## Calculations

DFT calculations, combined with the Broken-Symmetry (BS) approach were carried out to compute the exchange interactions. The calculations described herein were performed by Kuduva R. Vignesh. The B3LYP ${ }^{106}$ functionals were employed with Ahlrichs ${ }^{107-108}$ triple- $\zeta$ basis set for Ni atoms, a relativistic effective-core potential (ECP) LANL08(f) basis set ${ }^{109}$ for Mo atoms and $6-31 \mathrm{~g} *$ basis set for rest of the atoms as implemented in the Gaussian $09^{110}$ suite of programs to calculate the energies of the spin states as given in Table S 5 . The $J$ values were computed from the energy differences between the high spin $\left(\mathrm{E}_{\mathrm{HS}}\right)$ state calculated using single determinant wave functions, and the low spin $\left(\mathrm{E}_{\mathrm{BS}}\right)$ state determined using the Broken Symmetry (BS) approach developed by Noodleman. ${ }^{111}$ The BS approach has a proven record of yielding good numerical estimates of $J$ constants for a variety of complexes, ${ }^{112-113}$ such as dinuclear ${ }^{114-116}$, and especially, $4 \mathrm{~d} / 5 \mathrm{~d}$ metal complexes ${ }^{117}$ and polynuclear complexes. ${ }^{112,118-119}$ The following Hamiltonian is used to estimate the isotropic exchange interaction $(J)$.

$$
\text { (3) } \hat{\mathrm{H}}=-2 J\left(S_{\mathrm{Mo}} S_{\mathrm{Ni}}\right)
$$

In the case of a two spin system and using the spin Hamiltonian $\hat{\mathbf{H}}=\mathbf{- 2} \boldsymbol{J}_{i j} \mathbf{S}_{\mathbf{i}} \mathbf{S}_{\mathbf{j}}$, the energy difference between the high spin and low spin state is:

$$
\text { (4) } \mathrm{E}_{\mathrm{HS}}-\mathrm{E}_{\mathrm{BS}} / 2 \mathrm{~S}_{\mathrm{i}} \mathrm{~S}_{\mathrm{j}}=-2 \mathrm{~J}_{\mathrm{ij}}
$$

Considerations related to the self-interaction error in commonly used exchange functional, non-dynamic pair correlation effects, and the application of spin projection techniques to

DFT calculations led to the following equation to describe the energy difference: ${ }^{112-113,114-}$ 116
(5) $\mathrm{E}_{\mathrm{HS}}-\mathrm{E}_{\mathrm{BS}} /\left(2 \mathrm{~S}_{\mathrm{i}} \mathrm{S}_{\mathrm{j}}+\mathrm{S}_{\mathrm{j}}\right)=-2 J_{i j}$, where $\mathrm{S}_{\mathrm{i}}>\mathrm{S}_{\mathrm{j}}$.

Application of this formalism to half of the $\mathrm{Mo}^{\mathrm{II}}{ }_{6} \mathrm{Ni}^{\mathrm{II}}{ }_{12}$ complex that consists of six $\mathrm{Ni}^{\mathrm{II}}$ ions and three $\mathrm{Mo}^{\text {III }}$ with three $J_{1}$ interactions (between the inner ring $\mathrm{Ni}^{\text {II }}$ ions and $\mathrm{Mo}^{\text {III }}$ ions) and three $J_{2}$ interactions (between the outer $\mathrm{Ni}^{\mathrm{II}}$ ions and $\mathrm{Mo}^{\mathrm{III}}$ ions), leads to the following expressions for the differences between the energies for the nine spin states calculated by DFT methods:

$$
\text { (6) } E_{B S 1}-E_{H S}=2 J(2 * 1 * 1 / 2+1 / 2)=3 J_{1}
$$

For three possible $J_{1}$ interactions the expression becomes,

$$
\text { (7) } E_{B S 1}-E_{H S}=9 J_{1}
$$

Similarly, for three possible $J_{2}$ interactions the expression becomes,

$$
\begin{gathered}
\text { (8) } E_{B S 2}-E_{H S}=9 J_{2} \\
\text { (9) } J_{1}=1 / 9\left(184.47 \mathrm{~cm}^{-1}\right)=+20 \mathrm{~cm}^{-1} \\
\text { (10) } J_{2}=1 / 9\left(74.36 \mathrm{~cm}^{-1}\right)=+8.26 \mathrm{~cm}^{-1}
\end{gathered}
$$

Ab initio calculations were performed to compute the $g$ value and the zero-field splitting (D) of the $\mathrm{Ni}^{\mathrm{II}}$ ions and g value for the $\mathrm{Mo}^{\mathrm{III}}$ ions in $\mathbf{1}$ using ORCA 3.0 suite of programs. ${ }^{120}$ The BP86 functional was employed along with a scalar relativistic ZORA Hamiltonian and relativistic ZORA type of def2-TZVP basis set on the metal ions and on first coordination sphere, and def2-SVP for the rest of the atoms. The RI approximation with secondary TZV/J Columbic fitting basis sets were used along with increased integration grids (Grid 5 in ORCA convention). The tight SCF convergence was used throughout the
calculations ( $1 \times 10^{-8} \mathrm{Eh}$ ). The SOC contributions in the ab initio frame work were obtained using second-order perturbation theory as well as employing the effective Hamiltonian approach which enables calculations of all matrix elements to be made of the anisotropic spin Hamiltonian from the $a b$ initio energies and wave functions numerically. Here the state average-CASSCF (Complete Active Space Self-Consistent Field) method has been employed to compute the zero-field splitting. The active space comprises eight active electrons in five active d-orbitals ( $\mathrm{d}^{8}$ system; CAS $(8,5)$ ) for $\mathrm{Ni}^{\mathrm{II}}$ ion. With this active space, 110 triplet and 15 singlet states for the $\mathrm{Ni}^{\mathrm{II}}$ ion have been computed in the configuration interaction procedure.

Figure 50. One-half of the 7 complex, depicted above, was used for DFT calculations to compute the exchange interactions.

| :---: | :---: | :---: | :---: |
| $\left\{\mathbf{N i}(\mathbf{C N})_{\mathbf{2}} \boldsymbol{\}}\right.$ | First | 8751.7 | -48.3 |
|  | Second | 10199.1 | 20.7 |
|  | Third | 10556.6 | 19.6 |
|  | Fourth | 16398.0 | 0.06 |
| $\mathbf{\{ N i ( C N ) ( \mathbf { H } _ { \mathbf { 2 } } \mathbf { O } ) \}}$ | First | 7830.4 | 26.7 |
|  | Second | 8748.8 | 23.3 |
|  | Third | 11663.6 | -35.6 |
|  | Fourth | 15349.5 | -0.5 |

These calculations provide key evidence that corroborates the magnetic data; the results predict that both the $J_{1}$ and $J_{2}$ interactions are ferromagnetic in nature with the values of +20.5 and $+8.3 \mathrm{~cm}^{-1}$, respectively (Table 15). The ferromagnetic interaction values indicate that all $\mathrm{Mo}^{\text {III }}$ and $\mathrm{Ni}^{\text {II }}$ ions have spin-up configurations, leading to a ground state of $S=15$. These calculated ferromagnetic interactions are consistent with reported exchange constants values between $4 \mathrm{~d} / 5 \mathrm{~d}$ and $\mathrm{Ni}^{\mathrm{II}}$ ions. ${ }^{117,121}$

Ab initio CASSCF calculations were performed to compute the zero-field splitting (D) of Ni ions and $g$ parameters for both Ni and Mo ions in 7. Calculations suggest a $g$ value of $1.76\left(\mathrm{~g}_{\mathrm{x}}=1.03, \mathrm{~g}_{\mathrm{y}}=1.05\right.$ and $\left.\mathrm{g}_{\mathrm{z}}=3.19\right)$ for $\left\{\mathrm{Mo}^{\mathrm{III}} \mathrm{CN}_{7}\right\}$ center which is in close agreement with the reported values ${ }^{28}$ and rationalizes the expected room temperature $\chi_{m} \mathrm{~T}$ value when considering anisotropic Ni centers (Figure 51 and Table 17). Calculations predict a negative $D$ value $\left(-6.2 \mathrm{~cm}^{-1}\right)$ and $\mathrm{g}=2.23$ for the inner ring $\mathrm{Ni}^{\mathrm{II}}$ ions with two CN groups in axial positions $\left(\left\{\mathrm{Ni}(\mathrm{CN})_{2}\right\}\right)$, and a positive $D$ value $\left(+11.2 \mathrm{~cm}^{-1}\right)$ and $\mathrm{g}=$ 2.24 for the external $\mathrm{Ni}^{\mathrm{II}}$ ions with a $\mathrm{H}_{2} \mathrm{O}$ molecule and $\mathrm{a}-\mathrm{CN}$ group in their axial positions $\left(\left\{\mathrm{Ni}(\mathrm{CN})\left(\mathrm{H}_{2} \mathrm{O}\right)\right\}\right)$ (Figure 52 and Table 16). The computed crystal field splitting of the d orbitals for $\mathrm{Ni}^{\mathrm{II}}$ ions are depicted in Figure 53. Based on the orbital splitting in the $\left\{\mathrm{Ni}(\mathrm{CN})_{2}\right\}$ centers, the first excitation involves orbitals with the same $\left| \pm m_{l}\right|$ values ( $\mathrm{d}_{\mathrm{xy}}$ to $d_{x^{2}-y^{2}}$ ) resulting in a negative $D$ value as expected. In contrast, for the $\left\{\mathrm{Ni}(\mathrm{CN})\left(\mathrm{H}_{2} \mathrm{O}\right)\right\}$ centers, the first excitation occurs between the $\mathrm{d}_{\mathrm{xz}}$ and $\mathrm{d}_{\mathrm{yz}}$ orbitals (different $\left| \pm m_{1}\right|$ values) leading to a positive $D$ value. In both cases, the major contribution to the $D$ value arises from the triplet excited states (Table 17). The energy gaps between the ground and the first excited triplet states are relatively large, leading to either a small negative or positive D value.

## Conclusions and Future Studies

This work demonstrates that syntheses of octacyanocyanometallate containing compounds can be extended to the heptacyano derivatives. By using $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ in this synthesis instead of $\left[\mathrm{Mo}^{\mathrm{IV}}(\mathrm{CN})_{8}\right]^{4-}$, an analogue was isolated that exhibits coupling
between the Mo and Ni centers. The magnetic data and the calculations, taken together, provide strong evidence that the coupling is ferromagnetic in nature. This strategy can be useful in future work as a method to reliably obtain new molecules that contain $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$. Specifically, molcules of Cu and Mo, which are previously known with $\left[\mathrm{Mo}^{\mathrm{IV}}(\mathrm{CN})_{8}\right]^{4-}$, may provide interesting photomagnetic properties. ${ }^{122-126}$

Additionally, the newly reported compounds of Mo and the ligand DAPB provide a new route to pentagonal bipyramidal structures that contain $\mathrm{Mo}^{\mathrm{III}}$. While previous examples of SMMs that exhibit anisotropic exchange were limited to $\mathrm{Mn}^{\mathrm{II}}$, this new starting material may accelerate progress towards the realization of trinuclear compounds with other metal centers; the restricted geometry of the $\mathrm{Mo}^{\text {III }}$ center highly encourages the formation of Ising-type anisotropic exchange. The rich electrochemistry for this molecule is another excellent reason to pursue work with MoDAPB fragments - changing the oxidation state could lead to changes in other physical properties, including magnetism. A series which was able to probe many similar MoDAPB molecules may lead to interesting insights into exchange interactions and other phenomena. By systematically varying the identity of the capping metal groups and their geometry, new insights will be gained into the requisite parameters to improve polynuclear transition metal magnets.

## CHAPTER IV

## COMPOUNDS CONTAINING ORBITALLY DEGENERATE RHENIUM(II)

## Background

Heavy metal atoms, such as 5d transition metals, are important in the field of molecular magnetism due to the influence of more diffuse orbitals and increased spin-orbit coupling parameters. The increased spin-orbit coupling effects directly influence the anisotropy in the compounds whereas more diffuse orbitals lead to increased coupling. Both of these characteristics are desirable qualities for molecular magnets and could help to increase the operating temperature of SMMs. As the first example of a 5d-metal containing SMM, the molecule $\left[\left\{\mathrm{MnCl}_{4}\left\{\operatorname{Re}(\text { triphos })(\mathrm{CN})_{3}\right\}_{4}\right]\right.$, published by the Dunbar group in 2004, ${ }^{36}$ underscores the benefits of the incorporation of 5 d metal ions in magnetic compounds. Theoretical analysis of this molecule led to the conclusion that anisotropic exchange was responsible for the SMM behavior of the molecule. ${ }^{29}$ In spite of the observed SMM properties, the analysis revealed that the shape of the compound causes partial cancellation of the Ising-type anisotropy in the molecule. The anisotropy in the compound originates from the 3 -fold axis in the $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$moiety and the orientation of these moieties in $\left[\left\{\mathrm{MnCl}_{4}\left\{\operatorname{Re}(\text { triphos })(\mathrm{CN})_{3}\right\}_{4}\right]\right.$ results in less anisotropy than if the 3 -fold axes were arranged coaxially (see Figure 11).

As a result of that partial cancellation, a major goal of this work was to isolate a compound of $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$with a geometry that is more conducive to the development of Ising-type anisotropy. In the case of $\left[\left\{\mathrm{MnCl}_{4}\left\{\operatorname{Re}(\operatorname{triphos})(\mathrm{CN})_{3}\right\} 4\right]\right.$, there
is no organic ligand on the $\mathrm{Mn}^{\mathrm{II}}$ center to restrict the formation of an octanuclear complex. The introduction of a ligand that blocks some sites on the 3d metal center is expected to lead to the formation of compounds with different shapes than a distorted cube. In this vein, tmphen (3,4,7,8-tetramethyl-1,10-phenanthroline) is an attractive choice due to its steric bulk and propensity to facilitate crystallization. Pentanuclear trigonal bipyramidal compounds that take advantage of this ligand were previously reported by the Dunbar group, ${ }^{78,127-128}$ which is a very promising geometry for compounds of $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$ because of the manner in which the threefold axes on both of the $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$ moieties would align. It has been shown that the bulk of the triphos ligand would not hinder the formation of a pentanuclear structure of this type, as the previously synthesized compound $\left(\mathrm{Et}_{4} \mathrm{~N}\right)_{2}\left[\left((\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right)_{2}\left(\mathrm{Ln}_{\left.\left.\left(\mathrm{NO}_{3}\right)_{3}\right)_{3}\right] \cdot 4 \mathrm{MeCN} \text { adopts this arrangement. }{ }^{129} \text {. }{ }^{129} \text {. }}\right.\right.$ Despite the geometry of these structures, the very weak coupling to the lanthanide centers prohibits any Ising-type anisotropy from having a significant impact on the magnetism. It was hypothesized that replacing the lanthanide ions with 3 d transition metal ions in a similar architecture could generate Ising-type anisotropy through the mechanism of anisotropic exchange.

A second key design criterion involves the electronic structure of the 3d metal. Despite forming cubes with the formula $\left[\{\mathrm{MCl}\}_{4}\left\{\operatorname{Re}(\text { triphos })(\mathrm{CN})_{3}\right\}_{4}\right]$ where $\mathrm{M}=\mathrm{Mn}$, $\mathrm{Fe}, \mathrm{Co}, \mathrm{Ni}$, or Zn , only the Mn analog exhibits SMM behavior. This may be partially due to the introduction of a second source of anisotropy; other groups have reported that having multiple sources of anisotropy in polynuclear compounds sometimes results in diminished SMM behavior, as is the case for the series of compounds
$\left[\mathrm{L}_{\mathrm{NNN}} \mathrm{CoLnCoL}_{\mathrm{NNN}}\right] \mathrm{NO}_{3}\left(\mathrm{~L}=\mathrm{N}, \mathrm{N}^{\prime}, \mathrm{N}^{\prime \prime}-t r i s(2-h y d r o x y-3-m e t h o x y-\right.$ benzili- dene)-2-(aminomethyl)-2-methyl-1,3-propanediamine; $\mathrm{Ln}=\mathrm{Gd}, \mathrm{Tb}, \mathrm{Dy}$ ) (Figure 6). ${ }^{26-27}$ Notably, all SMMs that exhibit Ising-type anisotropic exchange couple an orbitally degenerate metal center with the isotropic 3 d metal $\mathrm{Mn}^{\text {II }} .{ }^{36-39}$ Another interesting choice that has yet to be explored is $\mathrm{V}^{\mathrm{II}}$. The more diffuse orbitals are expected to lead to stronger coupling, which may also enhance the barrier since the barrier height is proportional to the strength of the coupling in anisotropically exchange-coupled systems. Therefore, $\mathrm{V}^{\mathrm{II}}$ was used for the reactions with $\left[(\text { triphos }) \mathrm{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$in this chapter.

Three new compounds of $\left[(\text { triphos }) \mathrm{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$are reported herein, one of which successfully meets the criteria of lining up the threefold axes of the $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$ moieties. Two of these compounds, $\left[\left\{\mathrm{V}^{\mathrm{II}}(\text { tmphen })_{2}\right\}_{2}\left\{\operatorname{Re}(\mathrm{CN})_{3}(\text { triphos })\right\}_{2}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}(\mathbf{1 2})$ and the decomposition product $\left[\left\{\mathrm{V}^{\mathrm{II}}(\operatorname{tren})\right\}(\mu-\mathrm{CN}) \operatorname{Re}(\operatorname{triphos})\right]_{2}(\mu-\mathrm{O})(\mathbf{1 3})$ (tren $=$ triethylamine) demonstrate that the presence of coupling and an orbitally degenerate $\mathrm{Re}^{\mathrm{II}}$ center are not sufficient to guarantee Ising-type magnetic exchange. The third molecule $\left[\mathrm{V}^{\mathrm{II}}(\text { tmphen }) \mathrm{Cl}_{2}\right]_{3}\left[\operatorname{Re}(\mathrm{CN})_{3}(\text { triphos })\right]_{2} \cdot 2 \mathrm{MeCN}(14)$ is an excellent example to follow for future studies on molecules with the proper geometry to introduce Ising-type anisotropic exchange interactions.

## Experimental Details

## Synthesis

Syntheses were carried out under air free conditions using a nitrogen-filled glove box or Schlenk line outfitted with argon gas. The solvents were deoxygenated by sparging
with argon gas. Diethyl ether was purified using an MBRAUN purification system. $\left[\mathrm{V}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}$ and $\left(\mathrm{NEt}_{4}\right)\left[(\right.$ triphos $\left.) \mathrm{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]$ were prepared by literature methods; ${ }^{34,130}$ all other chemicals were purchased from commercial sources and used without further purification unless otherwise indicated.

## $\left[\left\{\mathbf{V}^{\mathrm{II}}(\text { tmphen })_{2}\right\}_{2}\left\{\operatorname{Re}(\mathrm{CN})_{3}(\text { triphos })\right\}_{2}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}(\mathbf{1 2})$

$\left[\mathrm{V}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}(34 \mathrm{mg}, 0.075 \mathrm{mmol})$ of and tmphen $(35 \mathrm{mg}, 0.15 \mathrm{mmol})$ were dissolved in 2 mL of $\mathrm{H}_{2} \mathrm{O}, 2 \mathrm{~mL}$ of MeOH , and 1 mL of MeCN . $\left(\mathrm{NEt}_{4}\right)\left[(\right.$ triphos $\left.) \mathrm{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right](50 \mathrm{mg}, 0.05 \mathrm{mmol})$ was also dissolved in 2 mL of $\mathrm{H}_{2} \mathrm{O}, 2 \mathrm{~mL}$ of MeOH , and 1 mL of MeCN . The solution of $\left(\mathrm{NEt}_{4}\right)\left[(\right.$ triphos $\left.) \mathrm{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]$ was added dropwise to the solution of $\left[\mathrm{V}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}$ and tmphen which led to a cloudy green solution. After standing overnight at room temperature, dark green, X-ray quality crystals were isolated, $12 \mathrm{mg}, 7.7 \%$ yield. Attempts to recover more product via $\mathrm{Et}_{2} \mathrm{O}$ diffusion were unsuccessful.

## $\left[\left\{\mathbf{V}^{\mathrm{II}}(\text { tren })\right\}(\mu-\mathrm{CN}) \operatorname{Re}(\text { triphos })\right]_{2}(\mu-\mathrm{O})(13)$

$\left[\mathrm{V}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}(23 \mathrm{mg}, 0.05 \mathrm{mmol})$ and tren $(8 \mathrm{~g}, 0.05 \mathrm{mmol})$ were dissolved in 2 mL of MeCN and 1 mL of MeOH and a separate sample of $\left(\mathrm{NEt}_{4}\right)\left[(\right.$ triphos $\left.) \mathrm{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right](34 \mathrm{mg}, 0.034 \mathrm{mmol})$ was dissolved in 2 mL of MeCN and 1 mL of MeOH . The $\left(\mathrm{NEt}_{4}\right)\left[(\right.$ triphos $\left.) \mathrm{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]$ solution was added dropwise to the solution of $\left[\mathrm{V}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}$ and tren, which resulted in a slightly cloudy orange solution. After standing overnight at room temperature, X-ray quality dark orange crystals were
isolated; $8 \mathrm{mg}, 10 \%$ yield. Attempts to recover more product via $\mathrm{Et}_{2} \mathrm{O}$ diffusion were unsuccessful.

## $\left[V^{\mathrm{II}}(\text { tmphen }) \mathrm{Cl}_{2}\right]_{3}\left[\operatorname{Re}(\mathbf{C N})_{3}(\text { triphos })\right]_{2} \cdot 2 \mathrm{MeCN}(14)$

$\left[\mathrm{V}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}(23 \mathrm{mg}, 0.05 \mathrm{mmol})$ and tmphen $(24 \mathrm{mg}, 0.1 \mathrm{mmol})$ were dissolved in 4 mL acetonitrile and added dropwise to a solution of $\left(\mathrm{NEt}_{4}\right)\left[(\right.$ triphos $\left.) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right](50 \mathrm{mg}, 0.05 \mathrm{mmol})$ in 4 mL of acetonitrile. The solution turned a dark blue color, and, after standing overnight, a small amount of $\mathrm{Et}_{2} \mathrm{O}$ was added. After 2 hours, a small crop of X-ray quality crystals was harvested from the solution. More $\mathrm{Et}_{2} \mathrm{O}$ was diffused into the solution in an attempt to recover more product, but no more crystals were isolated.

## Crystallography

Single crystals were selected under Paratone ${ }^{\circledR}$ oil with a MiTGen microloop or a glass fiber. Reflection data for $\mathbf{1 2}$ were collected under a stream of $\mathrm{N}_{2}$ at 100 K using beamline 15-AD-B at the Advanced Photon Source at Argonne National Laboratory. Reflection data for $\mathbf{1 3}$ and $\mathbf{1 4}$ were collected on a Bruker D8-QUEST diffractometer equipped with a $\mathrm{I} \mu \mathrm{S}$ Mo microsource $\left(\lambda=0.71073 \AA\right.$ ) under a stream of $\mathrm{N}_{2}$ gas at 100 K . The frames were integrated and a semi-empirical absorption correction was applied using SADABS ${ }^{68}$ within the software package included in the APEX3 software suite. ${ }^{69}$ The structure was solved using SHELXT ${ }^{70}$ and refined using SHELXL; ${ }^{71}$ OLEX2 was used as an interface for the solution and refinement. ${ }^{72}$ Small Q-peaks in the structure that were
consistent with the behavior of disordered solvent were removed using the SQUEEZE routine of the PLATON software package. ${ }^{73}$ Hydrogen atoms were placed in calculated positions.

## $\left[\left\{\mathbf{V}^{\mathrm{II}}(\text { tmphen })_{2}\right\}_{2}\left\{\operatorname{Re}(\mathbf{C N})_{3}(\text { triphos })\right\}_{2}\right]\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}(\mathbf{1 2 )}$

Compound $\mathbf{1 2}$ crystallizes in the space group $P \overline{1}$. The refinement required modeling of a disorder of the triflate anion, the phenyl rings that are part of the triphos ligand, and one tmphen ligand. No additional restraints or constraints were used. The two vanadium and two rhenium units form the corners of a square-like core, where the edges are the $\mathrm{CN}^{-}$ligands connected to one rhenium and one vanadium atom each. The metal centers adopt a distorted octahedral geometry with the Re and V metal ions being capped by a triphos moiety and two tmphen ligands respectively. Each rhenium unit is bound to the $\mathrm{V}(\text { tmphen })_{2}$ moieties through two of the three cyanide ligands with one terminal cyanide ligand. One square occupies into the unit cell and is accompanied by two triflate anions, so the square must have $\mathrm{a}+2$ charge. In this case, the metal centers can be assigned as $\mathrm{Re}^{\mathrm{II}}$ and $\mathrm{V}^{\mathrm{II}}$. The square sits on an inversion center so the asymmetric unit only contains half of the molecule. The Re-C bond lengths in the structure are 2.001(19) $\AA, 2.02(3) \AA$, and $1.996(17) \AA$. The V-N bond lengths to the cyanide ligands are $1.981(14) \AA$ and $1.986(17) \AA$. The square has angles at the corners of $86.374^{\circ}$ for C-Re-C and $99.800^{\circ}$ for $\mathrm{N}-\mathrm{V}-\mathrm{N}$.

Figure 54. Plot of the asymmetric unit in 12. Ellipses are drawn at the $50 \%$ probability level.

Figure 55. Full molecule of 12. Ligands are drawn in a wireframe mode to emphasize the structure of the cyanide-bridged core.

## $\left[\left\{\mathbf{V}^{\mathrm{II}}(\text { tren })\right\}(\mu-\mathrm{CN}) \operatorname{Re}(\text { triphos })\right]_{2}(\mu-\mathrm{O})(13)$

Crystals of $\mathbf{1 3}$ adopt the space group $\mathrm{P} 2_{1} / \mathrm{n}$. The asymmetric unit contains one-half of the molecule of one $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$moiety and one $\left[\mathrm{V}^{\mathrm{II}}(\text { tren })\right]^{2+}$ moiety. There is an $\mathrm{O}^{2-}$ bridge between the two $\mathrm{V}^{\text {II }}$ centers in the molecule which was assigned based on the charges of the other atoms in the structure. No outer-sphere ions were identified in the structure, so the molecule is assumed to be neutrally charged. The phenyl rings in the triphos ligands are somewhat disordered and were successfully modeled over two positions. The V-O bond length is $1.760(2) \AA$, which is consistent with other examples of linear V-O-V bonds with oxide. ${ }^{131-132}$ V-OH-V examples are typically bent and have distances close to $2.0 \AA$, while bridging $\mathrm{H}_{2} \mathrm{O}$ is also bent and typically has an even larger distance of 2.4 or $2.5 \AA .{ }^{133-136}$ The Re centers are six-coordinate with Re-C bond distances of 2.034(17) $\AA, 2.067(15) \AA$, and $2.034(15) \AA$. The $V^{\text {II }}$ ions are also six-coordinate with a V-N $\mathrm{N}_{\mathrm{CN}}$ bond distance of $2.068(12) \AA$. The $\mathrm{V}-\mathrm{N}_{\text {tren }}$ bond distances are $2.151(11) \AA$, $2.208(11) \AA, 2.162(11) \AA$, and $2.160(11) \AA$, with the longest bond being to the central N atom of tren. The angles around V are near $90^{\circ}$, with the $\mathrm{N}-\mathrm{V}-\mathrm{O}$ angles being the largest $\left(93.225^{\circ}-102.671^{\circ}\right)$ and the N-V-N angles being the smallest $\left(79.887^{\circ}-91.033^{\circ}\right)$.

$\left.{ }^{c} w \mathrm{R}=\left\{\Sigma\left[w\left(\mathrm{Fo}^{2}-\mathrm{Fc}^{2}\right)^{2}\right] / \Sigma w\left(\mathrm{Fo}^{2}\right)^{2}\right]\right\}^{1 / 2}$

## $\mathbf{N a}\left[V^{\text {II }}(t \operatorname{tmphen}) \mathrm{Cl}_{2}\right]_{3}\left[\operatorname{Re}(\mathbf{C N})_{3}(\text { triphos })\right]_{2} \cdot \mathbf{2 M e C N}(14)$

Compound $\mathbf{1 4}$ crystallizes in the space group $P \overline{1}$. The general shape is similar to previous examples of trigonal bipyramidal molecules - the three V units sit reside at the vertices of a triangular plane, which is capped by the two Re atoms. Interestingly, no sources of $\mathrm{Na}^{+}$or $\mathrm{Cl}^{-}$were added to the reaction; however, NaCl is a possible contaminant from the metathesis of NaCN and $\left(\mathrm{Et}_{4} \mathrm{~N}\right) \mathrm{Cl}$, which is used to make the $\left(\mathrm{Et}_{4} \mathrm{~N}\right) \mathrm{CN}$. $\left(\mathrm{Et}_{4} \mathrm{~N}\right) \mathrm{CN}$ is the cyanide source used to synthesize $\left(\mathrm{Et}_{4} \mathrm{~N}\right)\left[(\operatorname{triphos}) \mathrm{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]$. The $\mathrm{Cl}^{-}$ ions are the only negatively charged species that is close to the right size for the ligands on $\mathrm{V}^{\text {II }}$ in 14. The $\mathrm{Na}^{+}$was assigned by observing electron density in the center of the structure which fits with $\mathrm{Na}^{+} . \mathrm{Mg}^{2+}$ is also a valid assignment, but is less likely to be a contaminant. This positively charged ion has close contacts with the $\mathrm{CN}^{-}$ligands in the structure, so it is not logical to assign it as a negatively charged ion. Further work is necessary to confirm these assignments, preferably by synthesizing this molecule intentionally in a higher yield and measuring the magnetic properties.

The bridging cyanide ligands occupy the edges of the resulting trigonal bipyramid. While the phenyl rings are not sufficiently disordered to warrant extensive disorder modelling, SIMU restraints were required to obtain reasonable ellipsoids for several of the carbon atoms in those ligands. Some of the thermal ellipsoids of the cyanide ligands are distorted, and ISOR restraints were used to obtain reasonable ellipsoids for those atoms. The Re atoms are not significantly distorted from their typical, trigonally distorted octahedral geometry. Re 1 has Re-C bond lengths of $2.064(11) \AA, 2.050(11) \AA$, and 2.045(10) Å while Re2 has Re-C bond lengths of 2.055(10) $\AA, 2.052(10) \AA$, and 2.038(9)
$\AA$. The average length of the bonds is slightly longer for Re1, which can be attributed to the steric bulk of the tmphen ligands on the V centers, all three of which point towards Re1. The P-Re-P angles are less than $90^{\circ}$, ranging from $84.010^{\circ}-87.327^{\circ}$. The P-Re-C angles for cis positions vary from $98.118^{\circ}$ to $93.611^{\circ}$, while the trans $\mathrm{P}-\mathrm{Re}-\mathrm{C}$ angles vary from $175.177^{\circ}$ to $178.900^{\circ}$. The V atoms are also octahedral, with two ligands each of $\mathrm{N}_{\mathrm{CN}}, \mathrm{N}_{\text {tmphen }}$, and Cl . The bond lengths of the ligands around V are summarized in Table 20. The smallest cis $\mathrm{N}-\mathrm{V}-\mathrm{N}$ angle is $76.554^{\circ}$, which is smallest bite angle of the three tmphen moieties. The largest angle for each V center is the $\mathrm{Cl}-\mathrm{V}-\mathrm{Cl}$ angle, of which the largest is $97.806^{\circ}$ for V 1 .

The $\mathrm{V}-\mathrm{N}_{\mathrm{CN}}$ bond lengths do not indicate that there are distinct oxidation states of the V atoms; but the charge assignment for the Re and V centers is not straightforward due to the lack of counterions in the structure. The total negative charge is -12 (from 6 $\mathrm{CN}^{-}$and $6 \mathrm{Cl}^{-}$), but the total positive charge is only +11 if all V centers are divalent ( $3 \mathrm{~V}^{\mathrm{II}}$, $2 \mathrm{Re}^{\mathrm{II}}$, and $\mathrm{Na}^{+}$. Either the ion in the center of the structure is $\mathrm{Mg}^{2+}$ or there is one trivalent V center - there are no other obvious solutions to balance the charge in the structure. The V-N $\mathrm{N}_{\mathrm{CN}}$ bond lengths, however, are very similar to the bond lengths in $\left[\mathrm{V}^{\mathrm{II}}(\text { tmphen })_{2}\right]_{3}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{6}\right]_{2} \cdot(\mathrm{MeOH})_{12} \cdot(\mathrm{MeCN})_{2},{ }^{78}$ a previously reported trigonal bipyramidal molecule in the Dunbar group, which is reported with three $\mathrm{V}^{\mathrm{II}}$ centers. The average $\mathrm{V}_{\mathrm{CN}}$ bond length in $\left[\mathrm{V}^{\mathrm{II}}(\text { tmphen })_{2}\right]_{3}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{6}\right]_{2} \cdot(\mathrm{MeOH})_{12} \cdot(\mathrm{MeCN})_{2}$ is $2.028 \AA$, compared to $2.040 \AA$ in 14. More data are needed, especially magnetic measurements, to confidently assign the oxidation states of the V centers in 14.

## Magnetic Measurements

Magnetic measurements were performed on a Quantum Design MPMS-XL SQUID magnetometer equipped with a 7 T magnet. A polypropylene bag was used to secure the sample, and the diamagnetic contribution was subtracted from the raw data. Diamagnetic contributions from the sample were accounted for by using Pascal's constants. ${ }^{74}$

There is substantial theoretical work to reference when interpreting the magnetic data for compounds containing $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$. Theoretical treatments of both the starting material ${ }^{34}$ and the known SMM $\left[\{\mathrm{MnCl}\}_{4}\left\{\operatorname{Re}(\operatorname{triphos})(\mathrm{CN})_{3}\right\}_{4}\right]^{29}$ are relevant. In variable temperature static DC measurements of $\left[\mathrm{Et}_{4} \mathrm{~N}\right]\left[\operatorname{Re}(\right.$ triphos $\left.)(\mathrm{CN})_{3}\right]$, the $\chi \mathrm{T}$ value is a straight line, due to the influence of TIP. One cause of TIP, or Van Vleck paramagnetism, is the presence of low lying excited states in magnetic molecules and manifests as a consistent increase in $\chi \mathrm{T}$ as the temperature increases. In both $\left[E t_{4} \mathrm{~N}\right]\left[\operatorname{Re}(\operatorname{triphos})(\mathrm{CN})_{3}\right]$ and $\left[\left\{\mathrm{MnCl}_{4}\left\{\operatorname{Re}(\text { triphos })(\mathrm{CN})_{3}\right\}_{4}\right], \mathrm{Re}^{\mathrm{II}}\right.$ can be treated as a pseudo $S=1 / 2$ center as the strong trigonal ligand field on Re splits the ground cubic state ${ }^{2} T_{2}$ into ${ }^{2} A_{1}$ and ${ }^{2} E$, and the ${ }^{2} E$ term is the ground state. ${ }^{29}$ The low temperature magnetization data can reveal information about the coupling, as shown in the theoretical treatment of $\left[\{\mathrm{MnCl}\}_{4}\left\{\operatorname{Re}(\text { triphos })(\mathrm{CN})_{3}\right\}_{4}\right]$, despite the high anisotropy of the g-tensor of $\mathrm{Re}^{\mathrm{II}}$. Even in this case, where anisotropic exchange is involved, the saturation value of the low temperature magnetization was fit successfully with negative $J$ values, suggesting antiferromagnetic exchange between the $\mathrm{Mn}^{\mathrm{II}}$ and $\mathrm{Re}^{\mathrm{II}}$ centers.

Variable temperature static DC magnetic susceptibility measurements were performed on crushed crystals of $\mathbf{1 2}$ from 300 to 2 K under an applied field of 1000 Oe (Figure 59). The $\chi \mathrm{T}$ decreases from $4.5 \mathrm{emu} \cdot \mathrm{Kmol}^{-1}$ at 300 K to $2.2 \mathrm{emu} \cdot \mathrm{Kmol}^{-1}$ at 30 K , then drops precipitously to $.8 \mathrm{emu} \cdot \mathrm{Kmol}^{-1}$ at 2 K . The steady decrease in $\chi \mathrm{T}$ as the temperature is dropped is due to temperature independent paramagnetism (TIP), which, as mentioned above, is well documented in compounds of $\left[(\operatorname{triphos}) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-29,34,41,129}$ The increased slope of $\chi \mathrm{T}$ at low temperature suggests antiferromagnetic coupling. Zero-field splitting contributions will be absent from both $\mathrm{V}^{\mathrm{II}}$ and $\mathrm{Re}^{\mathrm{II}}$ in these geometries, because $\mathrm{V}^{\mathrm{II}}$ is isotropic $\left(\mathrm{t}_{2 \mathrm{~g}}{ }^{3}\right)$ and the $\mathrm{Re}^{\mathrm{II}}$ center in $\left[(\text { triphos }) \mathrm{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$which is a pseudo $S=1 / 2$ that does not have zero-field splitting. ${ }^{29}$ The 1.8 K magnetization data reach $1.9 \mu_{\mathrm{B}}$ in an applied field of 7T, but do not saturate. A value of $4 \mu_{\mathrm{B}}$ is the expected value for two $S=$ 3/2 $(g=2)$ centers coupled antiferromagnetically to two $S=1 / 2$ centers $(g=2)$ (Figure 60 ), which would lead to a ground state of $S=2$, but the highly anisotropic $\mathrm{Re}^{\mathrm{II}}$ center is not expected to match that value due to large anisotropy of the $g$ tensor.

Figure 59. Magnetic susceptibility plot of $\mathbf{1 2}$ from $300 \mathrm{~K}-2 \mathrm{~K}$ in an applied field of 1000 Oe.

Figure 60. Magnetization data at 1.8 K of $\mathbf{1 2}$ at fields up to 7 T (70,000 Oe).

Non-superposition of the isofield lines in the reduced magnetization data (Figure 61) indicates that there is anisotropy in the system, which could originate from the spin-orbit coupling from Re. Despite the presence of anisotropy, Figure 62 shows a clear lack of SMM behavior. This result is attributed to the overall geometry of the molecule which does not exhibit an alignment of the 3-fold axes of the Re centers. Previous work with $\left[\left\{\mathrm{MnCl}_{4}\left\{\operatorname{Re}(\text { triphos })(\mathrm{CN})_{3}\right\}_{4}\right]\right.$ shows that the $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$moiety has a proclivity to develop an easy axis along the $C_{3}$ axis, but this may not translate to easy axis anisotropy for molecules that are not symmetric about this axis. ${ }^{29}$ Despite evidence of coupling to $\mathrm{V}^{\mathrm{II}}$, the molecule is not 3 -fold symmetric, which confirms that this easy axis will not develop without such symmetry. Even if there were Ising-type anisotropy locally for each Re center, the failure to align the 3-fold axes of those metal centers precludes the development of Ising-type anisotropy for the molecule.

Figure 61. Reduced magnetization data for 12. Solid lines are a guide for the eye.

Figure 62. In-phase and out-of-phase susceptibility data for 12, measured at 2 K with applied static DC fields from 0-2000 Oe.

Variable temperature static DC magnetic susceptibility measurements were also performed on crushed crystals of $\mathbf{1 3}$ from 300 to 2 K under an applied field of 1000 Oe (Figure 63). The value of $\chi \mathrm{T}$ decreases linearly from $11.1 \mathrm{emu} \cdot \mathrm{Kmol}^{-1}$ to $2.8 \mathrm{emu} \cdot \mathrm{Kmol}^{-1}$ as the temperature is lowered from 300 K to 2 K . This behavior can be attributed entirely to TIP. The magnetization data at 1.8 K saturate near $4 \mu_{\text {B }}$ (Figure 64), which is consistent with a ground state of $S=2$ for isotropic centers. As mentioned for $\mathbf{1 2}$, though, $\operatorname{Re}^{\mathrm{II}}$ is expected to be very anisotropic in this geometry, so it may be coincidence that the magnetization data saturate at $4 \mu_{\mathrm{B}}$.

The reduced magnetization of $\mathbf{1 3}$ (Figure 66) reveal complete overlap of the isofield lines which indicates a lack of anisotropy in the molecule, but probing for SMM behavior (Figure 65) shows minor beginnings of an out-of-phase signal. It is difficult to interpret the presence of an out-of-phase signal when there is no evidence of magnetic anisotropy, but the signal is very weak, as might be expected for a geometry that is not 3fold symmetric around the $\left[(\text { triphos }) \mathrm{Re}^{\mathrm{Il}}(\mathrm{CN})_{3}\right]^{-}$anion.

Figure 63. Magnetic susceptibility data for 13 from $300 \mathrm{~K}-2 \mathrm{~K}$ with an applied field of 1000 Oe.

Figure 64. Magnetization data at 1.8 K for 13 at fields up to 7 T .

Figure 65. In-phase and out-of-phase susceptibility data for $\mathbf{1 3}$, measured at 2 K with applied static DC fields from 0-2000 Oe.

Figure 66. Reduced magnetization data for 13. Solid lines are a guide for the eye.

## Conclusions and Future Studies

The compounds $\mathbf{1 2}$ and $\mathbf{1 3}$ offer important insight regarding the need for specific geometries in compounds of $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$to induce anisotropy. Compound $\mathbf{1 4}$ demonstrates the possibility of obtaining the proper geometries to generate Ising-type anisotropic exchange. Future work should focus on optimizing reactions of this type so that the magnetic properties of such compounds can be fully explored.

TIP remains an issue in the characterization of compounds that contain $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$. Deeper theoretical treatment of the data would allow for more information to be gleaned by fitting the magnetization and magnetic susceptibility data.

Finally, it is noteworthy that reactions with $\mathrm{V}^{\mathrm{II}}$ resulted in no changes to the oxidation state of $\mathrm{Re}^{\mathrm{II}}$, which is critical to maintain orbital degeneracy in this system. Compound $\mathbf{1 4}$ is especially interesting due to the ambiguity of the oxidation states of the $\mathrm{V}^{\mathrm{II}}$ centers in the compound. Full magnetic characterization of this molecule is needed to confidently assign oxidation states for the V centers, which will have significant impact on the magnetic properties of the molecule. Three $\mathrm{V}^{\text {II }}$ centers may be the best for SMM behavior in this molecule, but it may also be interesting to observe the effects of a $\mathrm{V}^{\mathrm{II}} / \mathrm{V}^{\mathrm{II}} / \mathrm{V}^{\mathrm{III}}$ configuration, which cannot be ruled out based on the crystallographic data. In order to fully characterize this molecule, it should be pursued intentionally as a synthetic target, with stoichiometric amounts of $\mathrm{Cl}^{-}$and either $\mathrm{Na}^{+}$or $\mathrm{Mg}^{2+}$ in the reaction, so that the yield is not limited to a few small crystals. If $\mathbf{1 4}$ is found to exhibit SMM behavior, it would be another step towards fully understanding anisotropic exchange and using it to full effect in new heavy transition metal complexes.

## CHAPTER V

## CONCLUSIONS AND FUTURE WORK

The work described in this thesis was directed at exploring new directions for orbitally degenerate cyanometallate building blocks that are promising for the design of SMMs that exhibit anisotropic exchange coupling. While no SMMs were discovered, several new strategies were developed that may lead to new SMMs in the future.

In Chapter II, the potential for anisotropic exchange coupling with $\mathrm{Mo}^{\mathrm{III}}$ and lanthanide centers was investigated. The resulting chains of formula $\left\{\mathrm{K}\left[\operatorname{Ln}(\text { tmphen })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]\right\}(\mathrm{Ln}=\mathrm{Gd}, \mathrm{Tb}, \mathrm{Dy}, \mathrm{Ho}, \mathrm{Er})$ did not exhibit SCM properties, but there is evidence of antiferromagnetic coupling in several of the chains. The best approach for future work with these molecule is the incorporation of a radical bridging ligand, rather than a diamagnetic one, that will engender stronger direct coupling between the orbitally degenerate $\mathrm{Mo}^{\mathrm{III}}$ center and the lanthanide ion. In the case of superexchange, theoretical work on the $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ anion suggests that the best results are expected to occur with coupling an isotropic 3d metal to a pentagonal bipyramidal $\mathrm{Mo}^{\text {III }}$ center, so Gd is the best option for future work of this type.

In Chapter III, a new octadecanuclear wheel that incorporates $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ was described. This molecule is very similar to the octadecanuclear wheel that contains $\left[\mathrm{Mo}^{\mathrm{IV}}(\mathrm{CN})_{8}\right]^{4-}$, demonstrating that reactions of $\left[\mathrm{Mo}^{\mathrm{IV}}(\mathrm{CN})_{8}\right]^{4-}$ can be mimicked with $\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{CN})_{7}\right]^{4-}$ to introduce magnetic exchange interactions. New precursors were prepared that are expected to facilitate the synthesis of $\mathrm{Mo}^{\mathrm{III}}$ containing SMMs. By imposing a pentagonal bipyramidal geometry on $\mathrm{Mo}^{\text {III }}$ in $\left[\mathrm{Mo}^{\mathrm{III}} \mathrm{DAPB}(\mathrm{CN})_{2}\right]^{-}$, it is
expected that the orbital degeneracy is maintained. That assertion can be tested using magnetic data and if true, it should be possible to prepare novel, polynuclear metal complexes that can be studied for Ising-type anisotropic exchange and SMM behavior.

In Chapter IV, new reactions of $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$were presented that led to new compounds with interesting geometries. While none of the synthesized molecules were confirmed to be SMMs, one of them presents a geometry that is promising for future study, and may lead to significant advances in future work. In order to observe Ising-type anisotropic exchange, it is necessary to impose $C_{3}$ symmetry on compounds of $\left[(\text { triphos }) \operatorname{Re}^{\mathrm{II}}(\mathrm{CN})_{3}\right]^{-}$, and $\mathrm{Na}\left[\mathrm{V}^{\mathrm{II}}(\text { tmphen }) \mathrm{Cl}_{2}\right]_{3}\left[\operatorname{Re}(\mathrm{CN})_{3}(\text { triphos })\right]_{2} \cdot 2 \mathrm{MeCN}$ (14) meets this requirement. Future work should expand on this strategy with other 3d metals, including $\mathrm{Mn}^{\mathrm{II}}$, for comparison and a systematic study of anisotropic exchange.

The most promising compounds presented herein for generating Ising-type anisotropic exchange are $\mathrm{Na}\left[\mathrm{V}^{\mathrm{II}}(\text { tmphen }) \mathrm{Cl}_{2}\right]_{3}\left[\operatorname{Re}(\mathrm{CN})_{3}(\text { triphos })\right]_{2} \cdot 2 \mathrm{MeCN}$ $\left(\mathrm{NEt}_{4}\right)\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{DAPB})(\mathrm{CN})_{2}\right]$ (10), and $\mathrm{K}\left[\mathrm{Mo}^{\mathrm{III}}(\mathrm{DAPB})(\mathrm{CN})_{2}\right]$ (11). Magnetic measurements are needed for compound $\mathbf{1 4}$ to test the hypothesis that this molecule should exhibit Ising-type anisotropic exchange and therefore behave as an SMM. Compounds $\mathbf{1 0}$ and 11 are excellent new starting materials for future work that seeks to probe the conditions and requirements for Ising-type anisotropic exchange. By attaching different transition metal centers to the apical positions of a pentagonal, bipyramidal $\mathrm{Mo}^{\text {III }}$ center, it will be possible to tune the properties of the resulting molecules and draw important conclusions that can be leveraged to make progress in future experiments.

The incorporation of new organic ligands and new metal combinations can only serve to increase the knowledge in the field. As new methods and new molecules are developed, incorporating these ideas into novel electronic devices becomes increasingly promising. Anisotropic exchange is still poorly understood due to a dearth of results on the topic, but the work presented here offers good starting points for future work and may lead to promising directions for the field of molecular magnetism.
