Only the simpler kinds of been produced by geologic processes. For example, depth. Such a section exhibits what would be in a horizontal position. These sedimentary strata marine life existed when the oldest fossiliferous most valleys are the result of erosion by the streams seen in the side of a cutting many miles long and are now high above the sea, forming a plateau, and rocks were deposited. From time to time more that flow through them (see fig. 1), and the alluvial several thousand feet deep. This is illustrated in their change of elevation shows that a portion of the earth's mass has been raised from a lower to a higher level. The strata of this set are parallel, a relation which is called conformable.

The second set of formations consists of strata which form arches and troughs. These strata were once continuous, but the crests of the arches have been removed by degradation. The beds, like those of the first set, are conformable.

The horizontal strata of the plateau rest upon the upturned, eroded edges of the beds of the second set at the left of the section. The overlying deposits are, from their positions, evidently younger than the underlying formations, and the bending The figure represents a landscape which is cut and degradation of the older strata must have

> The third set of formations consists of crystalline schists and igneous rocks. At some period of their history the schists were plicated by pressure and traversed by eruptions of molten rock. But the pressure and intrusion of igneous rocks have not affected the overlying strata of the second set. Thus it is evident that a considerable interval elapsed between the formation of the schists and the beginning of deposition of the strata of the second set. During this interval the schists suffered metamorphism; they were the scene of eruptive activity; and they were deeply eroded. The contact between the second and third sets is another unconformity; it marks a time interval between two periods of rock formation.

The section and landscape in fig. 2 are ideal, but they illustrate relations which actually occur. The sections on the structure-section sheet are related to the maps as the section in the figure is related to The plateau in fig. 2 presents toward the lower the landscape. The profile of the surface in the

of the rocks, the thickness of the formations, and
