ABSTRACT

Development of a Heat-Balance Model for the Characterization of Wax Blockage in
Flowlines. (December 2004)

Ebiaye Valerie Ombu, B.S., Kwame Nkrumah University of Science and Technology

Chair of Advisory Committee: Dr. Stuart Scott

The presence of a blockage in a pipeline will alter the fluid dynamics of a flowing system in terms of the heat, mass and velocity characteristics. The analysis of the fluid dynamics is based on balances taken on the overall system to qualitatively and quantitatively assess the effects of the blockage. Pioneer work in the area of mass and momentum effects of blockages led to the development of blockage type curves useful in characterizing blockages from limited information. This work is an extension of previous work and is based on the application of a simplistic energy balance approach to characterize blockages in pipelines. The resulting heat models for the case of both a partially and fully-blocked flowline correctly predict the effect of wax deposition. Dimensionless temperature-based blockage maps developed here can be used in modeling unique cases where only two of the three necessary conditions are given. The heat model matches results from commercial software within a limited range of restricted flow conditions.

DEDICATION

This work is dedicated to all from whom I continue to learn kindness, wisdom and strength.

ACKNOWLEDGEMENTS

I wish to acknowledge first and foremost my Lord and Personal Savior, Jesus Christ, without whom, I am nothing.

I would also like to acknowledge my parents, Emmanuel and Viola Ombu, whose love and support have been unfailing.

Finally, I would like to acknowledge members of my committee: my advisor, Dr. Stuart Scott, thank you for everything; Dr. Tom Blasingame, I will never forget all your kindness to me; Dr. Yassin Hassan, thank you for your warmth and willingness to be on my committee and Dr. Malcolm Andrews; thank you for giving me a solid foundation in heat transfer and stepping in for my defense at the last minute.

INTRODUCTION

The exploitation of hydrocarbon resources is shifting more and more towards the development of offshore deepwater fields where flow assurance concerns increase exponentially and are critical to the economic viability of these projects. This shift has spurred growth in the area of flow assurance, resulting in significant technological advancements (multiphase pumps and meters) and increasingly sophisticated production techniques that have enhanced the economic attractiveness of offshore fields.

The term “flow assurance” has almost become a catch phrase in the oil industry in recent years. By no means a recent practice, flow assurance, a term thought to have been coined by Petrobras in the early 1990s as “garantia de fluxo” has been in existence from the commencement of commercial production of crude. It is exactly, as its name implies, the successful management of the vast array of issues involved in the production and transportation of crude, including the monitoring of the thermal and hydraulic behavior, PVT properties, and rheology of the crude; the prevention and control of blockages and leaks; and the maintenance of the mechanical integrity and stability of the entire production and processing facility. Flow assurance encompasses such issues as multiphase flow, blockage and leak prevention and control, slugging, system operability optimization, insulation, and corrosion.

This thesis follows the style and format of the *Journal of Petroleum Technology*.

One such critical issue, which serves as the focus of this research, is that of blockages. The majority of blockages or obstructions in flowlines can be traced to the deposition or precipitation of wax, asphaltenes, hydrates, scale, sand, or some combination of all these substances. One of the difficulties in dealing with blockages from more than one source is that each source (wax, asphaltenes, hydrate, sand, and scale) has unique properties such as phase envelopes, thermal conductivities and heat capacities and thus unique control techniques that sometimes conflict with one another and thus require some kind of trade-off. **Fig. 1** illustrates an arterial blockage from wax in a flowline.

Fig. 1—Illustration of a flowline plugged with wax.

Extensive research work on the actual mechanisms of blockage precipitation and deposition for wax is reviewed in the literature survey but does not serve as the focus of this study. The deposition models, which are developed from these theoretical

mechanisms, are often incorporated into simulation software and used for prediction purposes under actual conditions.

The traditional approaches to dealing with blockages have been both remedial with such intervention techniques as mechanical pigging, and preventive, using chemical inhibition schemes. These approaches, though the most viable options for handling blockages have significant drawbacks: Chemical inhibition is expensive and mechanical pigging involves considerable risk in the form of the constant threat of a stuck pig and the resulting tremendous cost of downtime to rectify the problem, or in the worst-case scenario, of losing the pipe entirely.

The problem of blockages does not have a unique panacea, rather a suite of tools, which collectively can be applied to the prevention, control, and remediation/removal of blockages. Analytical techniques that have been developed to characterize blockages serve as one such valuable tool. These include volume-based (mass) and friction-based (momentum) techniques developed by Scott and Satterwhite.¹ Their pioneer work including the application of the backpressure technique for blockage detection and the development of type curves are reviewed in the literature study. This study is an extension of their work but from a completely different perspective, the heat balance approach. It develops energy-based (heat) techniques for blockage characterization and presents a heat model quantifying the effects of a blockage on an overall energy balance from the original ideas set forth in the work of Chen et al.²

FOCUS OF RESEARCH

Wax deposition is a complex phenomenon requiring two basic models for its complete description; one model predicting the solid/liquid/vapor equilibria behind wax precipitation and the other, predicting the heat loss rate which controls the rate of wax deposition. This research is focused on developing a model for predicting the heat loss rate from flowlines in the presence of blockages.

Wellbore Heat Transfer vs. Flowline Heat Transfer

Heat Transfer from wellbore to formation is composed of heat transfer within the tubing and fluid-filled annulus; which is by convection and heat transfer through the tubing, casing walls and the formation; which is by conduction.³ Heat transfer into the formation is transient and was originally modeled by Ramey⁴ and improved for early times by Hasan and Kabir.⁵

Flowline heat transfer, which is the focus of this research, is composed primarily of convection from the flowline to the environment, though there is some conduction through the materials of the pipe wall and wax layer. Flowline heat transfer is being considered under steady-state conditions in this work.

BACKGROUND

The issue of blockages is critical in all installations but more so in offshore locations with installations of greater complexity, typically subsea completions tied back to existing platforms via flowlines of extensive lengths; and where accessibility is often limited. Among the serious economic consequences of blockages in pipelines is the obvious loss of revenue when production is deferred as the restriction reduces the flow capacity of the pipe. The problem of increased pumping pressure requirements as a result of the blockage, further compounded during startup as the waxy crude gels, leads to additional operational expenses.⁶ Wax deposition also reduces the capacity of process equipment and interferes with valve operation and instrumentation, causing system upsets and reducing the overall system operability efficiency.⁷ Undetected blockages can eventually plug the pipeline so severely that mechanical pigging is no longer an option and the entire pipe is lost. The loss of an offshore pipeline is disastrous, often leading to losses running into hundreds of millions of dollars.

Obviously, prevention, prediction, and early detection are the preferred options when dealing with blockages. Simulation software packages such as OLGA 2000⁸ and PIPESIM⁹ have built-in wax deposition modules based on thermodynamic models, which are able to estimate the degree of wax deposition. However, as with all simulation software, their application is limited by the inherent uncertainties. The prediction models upon which the simulation software are built, are still not considered to be very accurate, but they are believed to provide reasonable estimates of the rate of wax deposition and

thus provide a basis for assessing the needs for wax control.¹⁰ There is a clear need for as many predictive, analytical, diagnostic and remediation tools as possible for handling blockages thus forming the basis of this research. A review of the tools used in the handling of blockages is presented here under five categories:

1. Prediction,
2. Detection,
3. Prevention,
4. Remediation,
5. Analysis.

PREDICTION

The predictive tools are essentially models that incorporate the physical phenomena behind the formation and deposition of wax. The complete description of the mechanism of wax deposition encompasses both equilibrium models, which deal with the solid/liquid/vapor phase equilibria behind the wax precipitation, and heat models, which deal with the actual rate of deposition of the precipitated wax. These models form the basis of such simulation software as OLGA 2000 and PIPESIM.

Equilibrium Models

The equilibrium models developed are based on the process of wax precipitation and deposition. This necessitates a brief description of waxes and the chemistry behind their precipitation.

Waxes

Fig. 2–Structure of the various forms of wax.

Waxes/paraffins are high molecular weight, high carbon number (30 to 75) hydrocarbon compounds. Crude oil with a wax content greater than 10% is considered waxy and causes severe problems in the oil industry including clogging pipelines and forming arterial blockages that restrict flow, causing equipment deterioration, production slowdown and economic losses.

Waxes are characterized by two properties:

a) Wax Appearance Temperature/Wax Crystallization Temperature/Cloud Point:

This is the temperature at which wax crystals begin to crystallize and precipitate out of solution.

b) Pour Point: This is the temperature below which the crude ceases to flow. It is usually about 10-20 °F below the cloud point.⁶

Numerous equilibrium models have been proposed to describe the phase equilibria for wax deposition. The typical approach involves the application of two equilibrium models: a liquid/solid model and a vapor/liquid model. The equations that form the basis of any equilibrium are presented below.

The chemical potential of component i at temperature T in a liquid and solid phase, is:

$$\frac{\mu_i^L}{RT} = \frac{\mu_i^O}{RT} + \ln(x_i \gamma_i^L) \dots\dots\dots (1)$$

$$\frac{\mu_i^w}{RT} = \frac{\mu_i^O}{RT} + \ln(w_i \gamma_i^w) - \Delta H_i^f \left(\frac{1 - (T/T_i^f)}{RT} \right) \dots\dots\dots (2)$$

where μ^o = Chemical potential at standard state,

γ = Activity coefficient,

ΔH_f = Heat of fusion,

T_i^f = Fusion temperature,

x = Mole fraction in the liquid phase, and

w = Mole fraction in the wax phase.

For wax to be formed at a given temperature, the Gibbs free energy change (ΔG) for all possible wax compositions must be greater than zero as given by:¹²

$$\Delta G = \sum n_i^w \mu_i^w + \sum n_i^L \mu_i^L - \sum n_i^F \mu_i^F > 0 \dots\dots\dots (3)$$

where n_i is the number of moles of component i .

For thermodynamic equilibrium to be established between the liquid and wax phases, Eq. (4) must be satisfied.

$$\frac{w_i}{x_i} = \frac{\gamma_i^L}{\gamma_i^W} \exp \Delta H_i^f \left(\frac{1 - (T/T_i^f)}{RT} \right) \dots\dots\dots (4)$$

Won¹¹ developed a model from the fundamental equations above, which overestimated the cloud points.¹² Hansen *et al.*¹³⁻¹⁵ proposed polymer solution theory for the liquid

phase and treating the solid phase as an ideal mixture to improve the estimation and Pedersen *et al.* used solution theory for both the liquid and solid phases.¹⁴

Another model by Erbar¹⁵ applied by Majeed, Bringedal, and Overa¹⁶ to North Sea oils is presented here:

$$\frac{w_i}{x_i} = \left(\frac{\gamma_i^L}{\gamma_i^w} \right) \exp \left[\frac{\Delta H_i^f}{RT} \left(1 - \frac{T}{T_i^f} \right) + \frac{\Delta C_p}{R} \left(1 - \frac{T_i^f}{T} + \ln \frac{T_i^f}{T} \right) + \int_0^P \frac{\Delta V}{RT} dP \right] \dots (5)$$

where ΔC_p = Heat capacity change in fusion, and

ΔV = Volume change of fusion.

The vapor/liquid equilibrium is based on the traditional application of cubic equations of state such as the Soave-Redlich-Kwong equation.

There are three critical considerations with equilibrium models:

1. The determination of the potentially wax forming components and subsequent characterization of the heavy fraction into pseudocomponents,
2. The calculation of the equilibrium coefficients (*K*-values),
3. and the satisfaction of the material balance constraints.

The models are solved to satisfy all material balance constraints while providing equilibrium concentrations of the components in all three phases at varying temperatures. This variation in concentration with temperature dC/dT serves as input to the diffusion models (*see Molecular Diffusion in the section to follow*).

These models are incorporated into PVTsim; and PIPESIM as a separate wax deposition module.

Heat Models

Generally, wax deposition occurs when changes in the equilibrium condition of the flowing fluid reduce solubility. These changes could be changes in composition, temperature reduction below the wax appearance temperature (WAT), pressure drop resulting in loss of lighter ends and saturation of the crude, or the presence of nucleation sites.⁶ The rate of deposition is largely controlled by the amount of wax components dissolved in the crude and the rate of heat loss to the surroundings.

The physical phenomena describing wax deposition include molecular diffusion and shear dispersion. Molecular diffusion dominates at higher temperatures and heat fluxes while shear dispersion dominates at lower temperatures and heat fluxes.

Molecular Diffusion

This mechanism transports dissolved wax in solution across a temperature and concentration gradient. The bulk fluid ambient temperature difference forms the temperature gradient, which must be greater than zero for a net positive heat flux.^{14,15}

The transported wax is precipitated as a solid on the colder pipe wall and forms an immobile layer, which in turn creates a concentration gradient causing additional diffusion of the dissolved wax to the pipe wall. The concentration gradient is obtained from a thermodynamic calculation of the solid/liquid/vapor phase behavior.¹⁶ Molecular diffusion is the most significant contributor to wax deposition and is described mathematically by Fick's law.¹⁶⁻¹⁸

$$n = \rho D_m \frac{dC}{dr} = \rho D \frac{dC}{dT} \frac{dT}{dr} \dots\dots\dots (6)$$

$$D_m = \frac{B}{\mu} \dots\dots\dots (7)$$

where n = Mass flux,

ρ = Density of solid wax,

D_m = Molecular diffusion coefficient,

dC/dT = Concentration gradient (from equilibrium model),

dT/dr = Temperature gradient (from heat transfer analysis),

B = Constant for a particular crude, and

μ = Dynamic viscosity of the crude.

Shear Dispersion

Solid/particulate wax such as wax crystals, which normally travel with the mean speed and direction of the surrounding fluid, are transported from the turbulent core laterally to the pipe wall as a result of shearing of the fluid close to the pipe wall.¹⁶ This mechanism is controlled by the wall shear rate, the amount of wax out of solution, and the size and shape of particles. It becomes important when the precipitated wax content is high. The shear dispersion coefficient (D_s) is given by:

$$D_s = \frac{a^2 \gamma C_w^*}{10} \dots\dots\dots(8)$$

where a = Particle diameter,

γ = Shear rate of oil at the wall, and

C_w^* = Volume fraction concentration of wax out of solution at the wall.

(Note: The shear dispersion coefficient, D_s is added to the molecular diffusion coefficient when significant.)

Brownian motion and gravity settling are other wax deposition mechanisms but will not be discussed because their contribution is largely insignificant at the flowing conditions encountered in wells and pipelines.¹⁹

DETECTION

Unlike leaks that can in some cases be visually detected offshore with remotely operated vehicles, blockages are internal and thus pose a greater challenge to detect. The knowledge of the type of crude and its wax deposition potential, as determined from sampling and laboratory testing, is critical information that answers questions such as, Will wax form? Under what conditions? How much wax do we expect? Armed with this knowledge, production engineers can anticipate and design for the onset of wax deposition. The actual clues indicating the commencement of wax deposition/presence of blockages are wax crystals in produced crudes and wireline equipment, and unusual drop in production rate, wellhead pressure, or temperature due to Joule-Thompson effect.⁶

PREVENTION/CONTROL

A number of preventive methods currently used will be discussed in this section.

Chemical Control

This involves the use of wax inhibitors which come in two forms: wax crystal modifiers, which are polymers that inhibit or alter wax crystal growth thereby decreasing their pour point; and dispersants, which coat individual wax particles thereby preventing their agglomeration and subsequent deposition. Inhibitors also act to decrease the wax appearance temperature, increasing the non wax-forming operational envelope.

Needless to say, chemical control is costly. Monthly expenditures on chemical injection are estimated to run as high as \$800,000, which when added to the value of deferred production (due to the blockage) could result in annual losses up to \$25 to 30 million for a single oil well.²⁰

Thermal Methods

They serve a dual purpose of prevention and remediation of blockages. Insulation and active heating are the primary options used to maintain the bulk fluid temperature above the wax appearance temperature. Procedures such as steaming the flowlines, installing bottomhole heaters, and hot oil/water circulation are implemented to melt the paraffin deposit.²¹ Obvious drawbacks to these procedures include the considerable cost of energy for heating and the difficulty/impracticality of heating in hostile environments.²²

A chemical process known as the Nitrogen Generating System (SGN) created by Petrobras (also available by Baker-Hughes) which is based on strongly exothermic reactions of salt solution mixtures is used to melt paraffin deposits.²³

Production/Completion Techniques

These involve the use of plastic and coated pipes, application of backpressures, and the use of improved handling facilities.⁶ The pressure boost provided by multiphase pumping, an emerging technology, is also thought to have an additional advantage of shifting flowing/production conditions out of the hydrate- and wax-forming operational envelope and also controlling pipeline slugging.²⁴

Distributed Temperature Sensors²⁵ which are basically fibreoptic sensors are employed by companies such as Schlumberger to provide accurate, real-time temperature measurements necessary for a proactive approach to flow assurance. They provide critical information that aid in signaling the onset of leak and blockage detection, optimize energy requirements for flowline heating and reduce chemical injection.²⁵ This ultimately aids decision-making leading to prompt and effective remedial action as well as substantial cost savings.

Other commercially available tools for dispersion are magnetic and ultrasonic techniques. Magnetic techniques are based on the creation of a magnetic field that alters the chemical, mechanical, and electrical properties of the crude reducing the kinetics of

deposition and altering the cloud point mechanism. These flow-conditioning tools are in large-scale operation in China²⁶ and were the subject of investigation by Petrobras.²³

Ultrasonic techniques involve the use of a movable source of electromagnetic radiation, such as in an electromagnetic pig. As the pig moves, the plug absorbs intense electromagnetic radiation, heats up and melts. Effective melting of the dielectric plug is achieved with the source moving along the pipeline as the solid–liquid interface propagates.²⁷

Mechanical Techniques

The main mechanical techniques are pigging, wireline cutting, and through flowline cutting, which are all variations of the same concept of running a scraper through a pipeline.

Pigging

The most common method for removing accumulated wax deposits, the pig is sent down the line, carried along by the flow of crude, and mechanically scrapes off the wax, re-dispersing it in the bulk oil in front of the pig. This operation can be a successful, cost-effective method for managing paraffin deposits in flowlines and pipelines provided that a regularly scheduled pigging program is initiated upon commissioning.²⁸

The numerous pig designs range from simple spheres, to foam pigs, to bristle pigs, to very aggressive pigs used for cleaning out severe deposits. The basic breeds of pigs are the poly pig, which is equipped with soft foam used often for gauging an unknown environment inside of a pipeline; the jet pig, armed with steel brushes used to scrape off solid, heavy deposits; and the super pig, which can be equipped with a variety of attachments, from brushes and cups to bi-directional disks.²⁶ There are also intelligent/ smart pigs known as Inline Inspection Tools (ILI),²⁹ which are equipped with a computer and battery pack and are used more for inspection to ensure pipeline integrity than for actual paraffin remediation.

Generally, in the early phase and design evaluation, a maximum wax layer thickness of 2 to 3 mm is used as the criterion for pipeline pigging.¹⁰

Wireline Cutting/Through-Flowline Cutting (TFL)

These operations involve pumping a cutting tool down the flowline and into the wellbore to cut wax deposits. Though TFL is not yet a common practice, it has the advantage of being able to remediate subsea flowlines and wellbores from a distant platform. It was used in the Pompano Paraffin Calibration Field Trials to clear of wax deposits before well testing.²⁸ A drawback of wireline cutting is its costliness.

Microbial-Based Techniques

These are commercially available microbial formulations used to treat paraffin deposition in the oil field. They have been successfully tested in fields in China²⁶ and are considered cheaper than most of the methods outlined above when readily available.

The bottom line is that there is no unique panacea to paraffin prevention and remediation; but rather the successful and unique combination of the solutions listed above must be determined on a case-by-case basis and, unfortunately, sometimes by trial and error to solve wax problems.

ANALYSIS TECHNIQUES

By analytical methods, we mean the various “simplistic” methods that have been developed from readily available pressure and volume data. The idea behind these analysis techniques is that they provide vital information that helps in decision making, such as the optimal amount of chemicals to be used; they also aid in the determining the risk of pigging and the type of pig to be run.³¹

The three basic analyses are mass, momentum and energy balance approaches. The common thread in all approaches is the qualitative and quantitative assessment of the deviation of the response when partially or fully-blocked from the baseline response.

Mass/Volume-Balance Approach

The mass/volume balance method, developed by the onshore industry, is one of the most accurate methods. It is based on a blockage factor defined as the ratio of the volume of a partially blocked pipe of radial geometry relative to its unblocked volume. This ratio is obtained experimentally by bleed-off tests at the time the pipe is commissioned and after the blockage occurs. It requires accurate metering of inlet and outlet flow rates, which is often a limitation due to difficulties in obtaining precise measurements of inlet flow rates. The blockage factor as defined for a pipe of radial geometry is:

$$F_{VB} = \frac{V_B}{V_P} = 1 - \frac{L_B}{L_P} \left[1 - \left(\frac{d_B}{d} \right)^2 \right] = 1 - L_{BD} (1 - d_{BD}^2) \dots \dots \dots (9)$$

where L_{BD} is the dimensionless blockage length, and d_{BD} the dimensionless blockage diameter.

The volumes of the blocked and unblocked pipeline are obtained from the basic definition of isothermal compressibility:

$$C_t = -\frac{1}{V_p} \left(\frac{\partial V_p}{\partial P} \right)_T \dots \dots \dots (10)$$

$$C_t = C_p + C_L \left(\frac{V_L}{V_P} \right) + C_B \left(\frac{V_B}{V_P} \right) \dots\dots\dots (11)$$

where C_p , C_L and C_B are the pipeline, liquid, and blockage compressibilities which can be estimated within the pressure range of interest.

The slope (dV_p/dP) can be obtained from volume bleed-off tests conducted at baseline conditions when the pipe is unblocked and at later times when the pipe is blocked. The blockage factor then becomes:

$$F_{VB} = \frac{V_B}{V_p} = \frac{\frac{1}{C_t} \left(\frac{\partial V_p}{\partial P} \right)_{\text{blocked}}}{\frac{1}{C_t} \left(\frac{\partial V_p}{\partial P} \right)_{\text{baseline}}} \dots\dots\dots (12)$$

Momentum-Balance Approach

The momentum-balance approach is based on the fact that a blockage reduces the hydraulic diameter of a pipe and increases the frictional pressure losses. The basic equations are:

$$\frac{dP}{dx} = \frac{2f\rho v^2}{d} \dots\dots\dots (13)$$

and

$$\Delta P_f = 4f \frac{L \rho}{d} \left(\frac{4Q_{flow}}{\pi d^2} \right)^2 \dots\dots\dots (14)$$

Substituting the expression for friction factor and further manipulation yields:

$$(d_i - 2\delta_w)^{5-n} = \frac{2c\rho L}{\Delta P_f} \left(\frac{\mu}{\rho} \right) \left(\frac{4Q_{flow}}{\pi} \right)^{2-n} \dots\dots\dots (15)$$

where δ_w is the wax thickness.

This method, originally reported by Weingarten and Euchner,³² has been used successfully in experimental work by several investigators to determine wax thickness and wax appearance temperature.

From Eq. 14, Scott and Satterwhite¹ developed the backpressure technique of monitoring partial blockages in pipelines.

The backpressure equation for a single-phase liquid is given by:

$$Q = J (P_1 - P_3)^n \dots\dots\dots (16)$$

For a partially blocked pipe, the expression becomes:

$$Q = JF_{FB} (P_1 - P_3)^n, \dots \dots \dots (17)$$

where the constant J and the exponent n have different expressions for fully rough flow and smooth pipe.

They defined the friction-based factor (F_{FB}) by writing out Eq. 14 for both the partially blocked and unblocked sections of a pipeline. Eq. 18 gives the expression for F_{FB} for fully rough flow and Eq. 19 for smooth pipe;

$$F_{FB} = \frac{1}{\sqrt{\left(\frac{f_B}{f}\right)\left(\frac{L_B}{L_p}\right)\left(\frac{d}{d_B}\right)^5 + 1 - \left(\frac{L_B}{L_p}\right)}} \dots \dots \dots (18)$$

$$F_{FB} = \frac{1}{\sqrt{\left(\frac{L_B}{L_p}\right)\left(\frac{d}{d_B}\right)^{4.8} + 1 - \left(\frac{L_B}{L_p}\right)}} \dots \dots \dots (19)$$

This blockage factor (F_{FB}) represents the effect of the blockage evidenced by a very subtle deviation of the backpressure plot from the characteristic linear baseline response. Multirate tests are used to determine the baseline values of J and n to be able to separate out the friction-based factor as blockages develop.

The volume- and momentum-balance approaches can each be used to detect blockages in pipelines, but the actual characterization of the blockage requires the simultaneous solution of the volume- and friction-based factor equations (Eqs. 12 and 18 or 19) for blockage length (L_B) and diameter (d_B).

Energy-Balance Approach

The third approach, which is the focus of this research, is based on a heat balance. This is a novel approach that has been explored by such investigators as Kaminsky to interpret preliminary test data from the Wax Joint Industry Project currently underway at the University of Tulsa.²

The heat-balance approach is based on the concept that blockage resulting from the deposition of a wax layer contributes an additional layer of resistance to heat flow. This wax layer has an insulating effect that can be detected in the observed temperature drop from the inlet to the outlet of the pipeline. This insulating effect, quantified by the deviation of the observed temperature drop from the expected temperature drop, is directly related to the thickness and thermal conductivity of the wax deposited.

The original model,² which serves as the building block of this research, is shown below:

$$\frac{T_m - T_e}{q_o} = \frac{1}{h_i} \frac{r_o}{r_i - \delta_w} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \delta_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}, \dots (20)$$

where q_o = Heat lost to the surroundings,

h_i = Internal film heat transfer coefficient,

h_o = Outside film heat transfer coefficient,

k_p = Thermal conductivity of the pipe,

k_w = Thermal conductivity of wax layer, and

δ_w = Wax thickness.

THE HEAT-BALANCE MODEL FOR A FULLY-BLOCKED PIPELINE

The base relations are summarized below (see Appendix A for details of development of the model).

1) Fundamental Heat-Balance equation

$$\Delta Q = Q_{in} - Q_{out} = 0 \dots\dots\dots (21)$$

where ΔQ = Change in heat energy,

Q_{in} = Heat energy entering the pipe, and

Q_{out} = Heat energy leaving the pipe.

2) Heat Loss Components

$$Q_{out} = Q = Q_1 = Q_2 = Q_3 = Q_4 \dots\dots\dots (22)$$

where Q_1 = Internal convection (from the fluid),

Q_2 = Conduction through the wax layer,

Q_3 = Conduction through the pipe wall, and

Q_4 = External convection (to the ambient air).

3) Heat Loss Expression

$$Q = UA \Delta T = \frac{T_{amb} - T_{mi}}{\frac{1}{h_i A_i} + \frac{\ln\left(\frac{r_i}{r_i - \delta_w}\right)}{2\pi L k_w} + \frac{\ln\left(\frac{r_o}{r_i}\right)}{2\pi L k_p} + \frac{1}{h_o A_o}} \quad \dots (23)$$

4) Heat Input (Q_{in})

$$Q_{in} = q = \dot{m} C_p dT_m \dots\dots\dots (24)$$

5) Intermediate Heat-Balance Expression

$$\dot{m} C_p dT_m = q'' A = UA \Delta T = U(P dx) \Delta T, \dots\dots\dots (25)$$

where P is the perimeter of the pipe.

6) Intermediate Heat-Balance Expression (after integration)

$$Q = \dot{m}C_p(\Delta T_o - \Delta T_i) = \frac{-2\pi r_o L_p \left(\frac{(T_{amb} - T_{mo}) - (T_{amb} - T_{mi})}{\ln \frac{T_{amb} - T_{mo}}{T_{amb} - T_{mi}}} \right)}{\frac{r_o}{h_i(r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \dots (26)$$

7) Mass Flow Rate Expression

$$\dot{m} = \rho Q_{flow} \dots (27)$$

8) Heat-Balance Model

$$\frac{T_{amb} - T_{mo}}{T_{amb} - T_{mi}} = \exp \left\{ \frac{-\bar{U}A_o}{Q_{flow} \rho C_p} \right\} \dots (28)$$

where;

$$\bar{U} = \frac{1}{\frac{r_o}{h_i(r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \dots (29)$$

9) Final Heat-Balance Model for a Fully-Blocked Pipeline (expressed as a temperature drop)

$$T_{mi} - T_{mo} = T_{amb} \left[\exp \left\{ \frac{-\bar{U} A_o}{Q_{\text{flow}} \rho C_p} \right\} - 1 \right] + T_{mi} \left[1 - \exp \left\{ \frac{-\bar{U} A_o}{Q_{\text{flow}} \rho C_p} \right\} \right] \dots\dots\dots (30)$$

With this model, given a certain wax thickness and other pipe and ambient properties, the temperature drop of the fluid from inlet to outlet can be estimated.

TEMPERATURE SKIN FACTOR FOR A FULLY-BLOCKED FLOWLINE

The concept of skin from the reservoir has been extended to pipe flow, in which case skin refers to any blockage that obstructs pipe flow. From a pressure drop analysis, the skin consists of an additional pressure drop term that increases the overall pressure drop in the pipe. Similarly, a skin factor can be derived from a temperature drop analysis, where the skin in this case would account for the insulating effect of the wax layer. The skin term would directly affect the overall heat transfer coefficient (\bar{U}) and in this case, would have an inverse relationship to the observed temperature drop from pipe inlet to pipe outlet. The skin term can be extracted from a comparison of the overall heat transfer coefficient expression written for an unblocked and blocked pipeline.

The heat transfer expressions for a blocked and unblocked pipe are given by Eqs. 31 and 32 respectively.

$$\bar{U} = \frac{1}{\frac{r_o}{h_i(r_i - \delta_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \delta_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \dots\dots\dots (31)$$

For an unblocked pipe, where $\delta_w = 0$,

$$\bar{U} = \frac{1}{\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \dots\dots\dots (32)$$

Comparing the two equations, we can extract a skin factor from the denominator of the expression for the blocked pipe as;

$$S = \frac{r_o}{h_i(r_i - \delta_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \delta_w} - \frac{r_o}{h_i r_i} \dots\dots\dots (33)$$

The general expression for the heat transfer coefficient including the skin factor is:

$$\bar{U} = \frac{1}{\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} + S} \dots\dots\dots (34)$$

The unit of this skin factor is $\text{m}^2\text{K/W}$. There is a direct relationship between the size of blockage (δ_w) and the skin factor. The greater the blockage, the greater the skin factor and the lower the temperature drop, as can be seen from the general expression for the blocked pipe.

GRAPHICAL REPRESENTATION OF HEAT-BALANCE MODEL FOR A FULLY-BLOCKED PIPELINE

Flowline and Fluid Properties

These relationships can be illustrated graphically for an actual pipeline. The pipeline is assumed to be ‘fully-blocked’, i.e. there is a blockage of uniform circumferential and longitudinal thickness that extends along the entire pipeline length. The characteristics of a North Sea pipeline selected from the work of Labes-Carrier¹⁰ are summarized in **Table 1**.

Table 1—Characteristics of North Sea Pipeline Selected

Parameter	Value
Pipe Length	43 km
Pipe ID	0.38 m
Pipe OD	0.4054 m
Material	Stainless Steel

Arbitrary, but realistic values selected for the fluid properties (oil and air) are summarized in **Table 2**.

Table 2–Fluid Properties

Property	Oil	Ambient Air
Density (ρ), kg/m ³	875.32	1.271
Viscosity (μ), cp	1.0603	0.01748
Specific Heat Capacity (C_p), J/kgK	1890	1005
Thermal Conductivity (k), W/mK	0.18	0.02465

The thermal conductivity of the wax (k_w) is assumed to be equal to 0.25 W/mK.

Convective Heat Transfer Coefficients

Internal Convective Coefficient (h_i): It is estimated from the Dittus-Boelter correlation.³¹

$$N_{NU} = 0.023 N_{RE}^{4/5} N_{PR}^n \dots\dots\dots (35)$$

$$N_{NU} = \frac{h_i D_i}{k} \dots\dots\dots (36)$$

$$N_{RE} = \frac{4 \dot{m}}{\pi D \mu} \dots\dots\dots (37)$$

$$N_{PR} = \frac{C_p \mu}{k} \dots\dots\dots (38)$$

where $n = 0.3$ for cooling and 0.4 for heating (cooling is assumed; i.e., $T_s < T_m$), N_{NU} is the Nusselt number, N_{PR} the Prandtl number, and N_{RE} the Reynolds number. The Dittus-Boelter³³ correlation is applicable within the specified ranges below:

$$0.7 \leq N_{PR} \leq 160$$

$$N_{RE} \geq 10,000$$

$$\frac{L}{D} \geq 10$$

External Convective Coefficient (h_o): The simplest case scenario is considered here with the pipeline elevated 1 m above ground level and standing in ambient air of velocity less than 0.5 m/s. In this case, natural convection dominates and the recommended PIPESIM value for h_o of $4 \text{ Wm}^{-2}\text{K}^{-1}$ is used.⁹

The ambient air temperature was taken as 0°C and the pipe wall surface temperature as 32°C . The bulk fluid temperature at the inlet (T_{mi}) was taken as 35°C and all fluid thermodynamic properties were evaluated at this temperature with the assumption that the variation from pipe inlet to outlet is small.

The graphical results for variations in skin factor and flow rate are presented in **Figs. 3 to 6**.

Fig. 3—Temperature drop variation with flow rate (Cartesian plot).

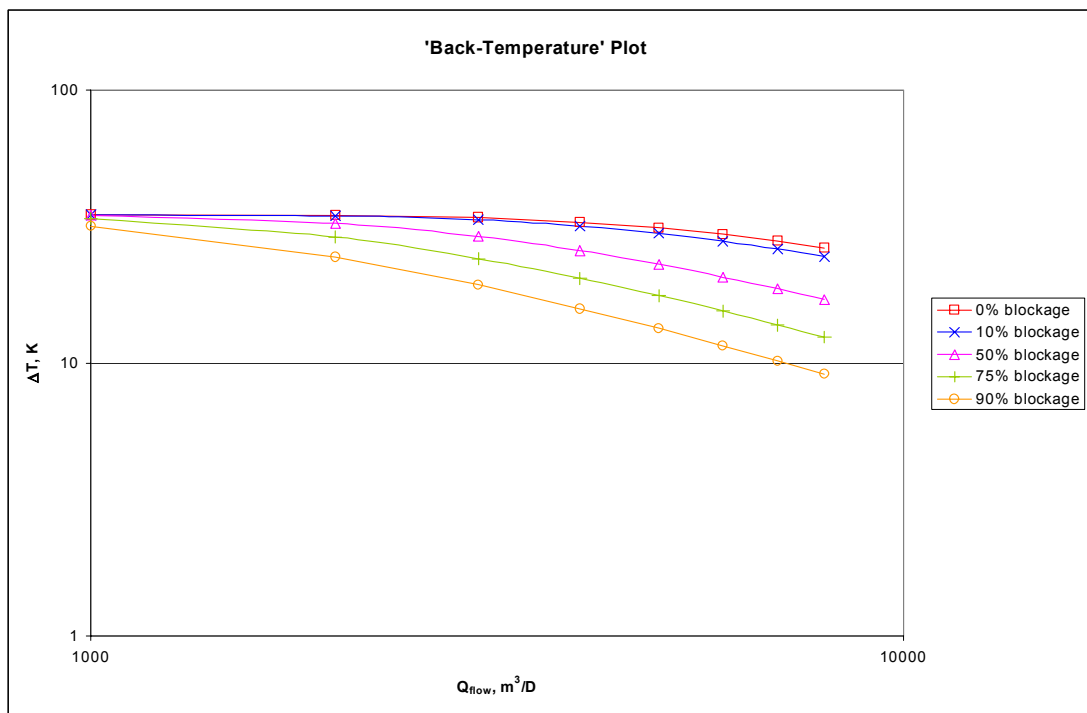

Fig. 4—Temperature drop variation with flow rate (back-temperature plot).

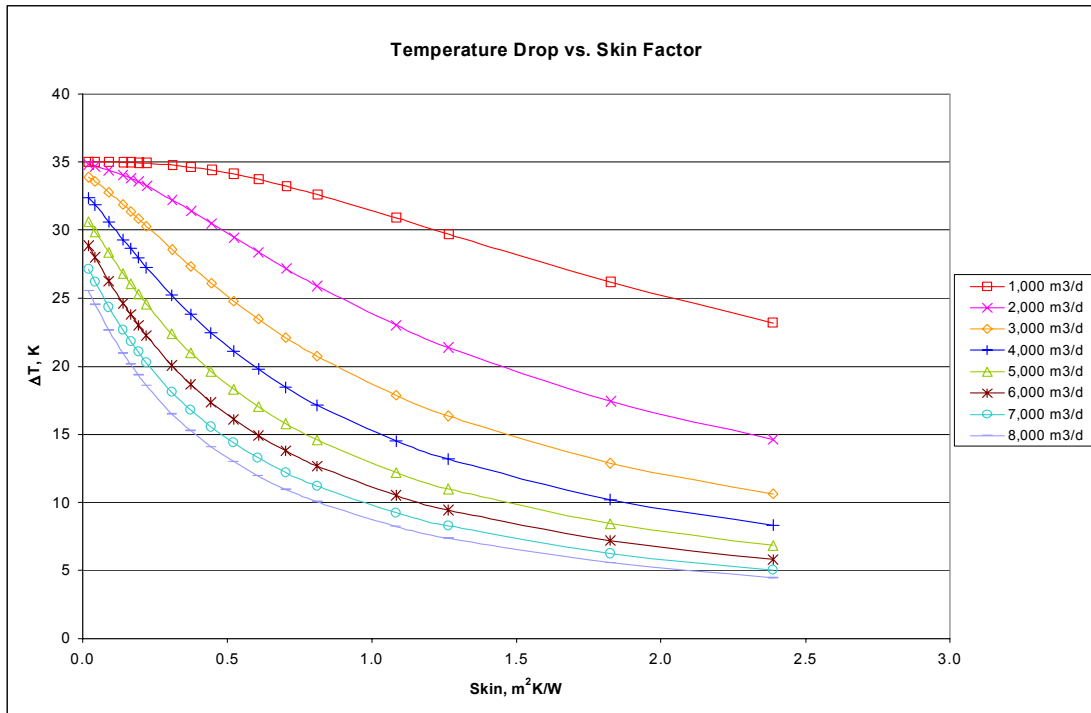

Fig. 5—Temperature drop variation with skin factor.

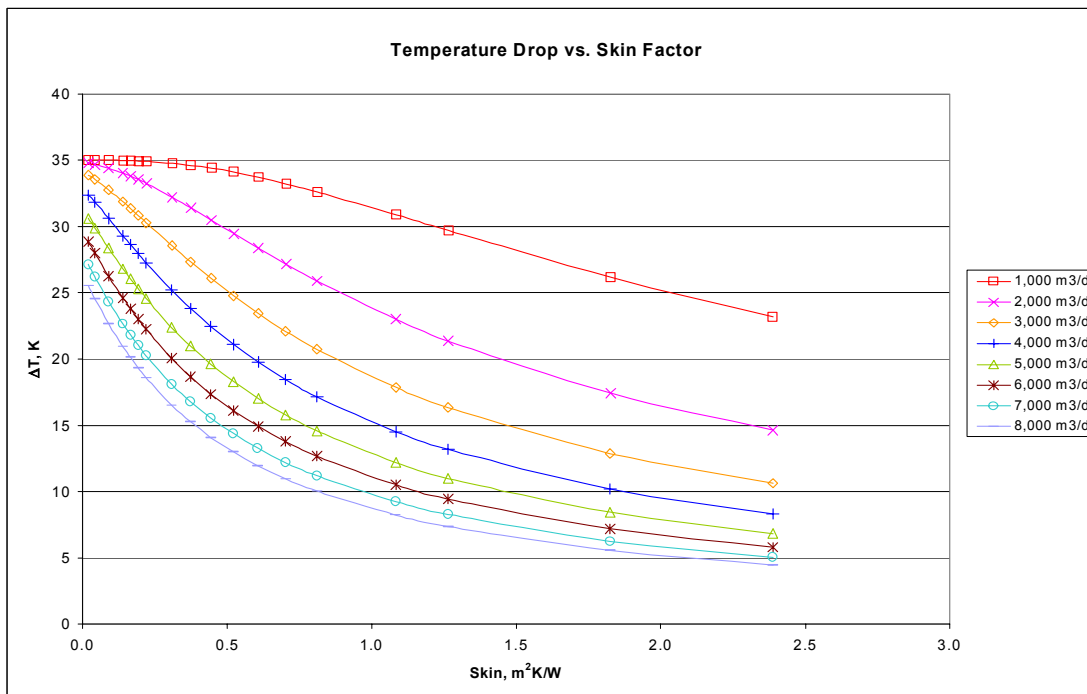

Fig. 6—Outlet temperature variation with flow rate and blockage.

Discussion

Fig. 3 shows that the greater the flow rate, the lower the temperature drop because higher flow rates imply greater volumes of fluid, higher heat contents (mC_p) and a greater overall retention of heat in the system. At higher flow rates, the heat transfer (loss) rate is lower and therefore the temperature drop from pipe inlet to outlet is lower. This is consistent with results obtained by Golzynski and Niesen;³⁴ they state, “At lower flowrates, the temperature losses to the environment will be increased, as there is less input to the system. The lower flowrates contribute less overall thermal mass to the system, and, as such, cannot maintain the high temperatures as easily as the flowrates do.”

Fig. 4, essentially a “back temperature” representation of the information in Fig. 3, depicts the effect of a uniform blockage on fluid flow in a pipeline as a departure from the zero-blockage line. A blockage in a pipeline will manifest on a ‘back-temperature’ plot as a shift in trend below the zero-blockage line: the greater the blockage, the greater the shift. The ‘shift’ is as a result of the insulating effect of the wax blockages deposited. As the blockage increases in cross-sectional area, it reduces the overall heat loss rate causing the temperature drop from pipe inlet to outlet to decrease.

Fig. 5 clearly illustrates the inverse relationship between temperature drop from pipe inlet to outlet and skin factor. As the skin factor increases, the temperature drop

decreases. Also, at higher flow rates, the temperature drop is more sensitive to skin factor than at lower flow rates.

Fig. 6 shows the variation in outlet temperature with flow rate with different extents of blockage. Clearly, the outlet temperature is higher than expected when a blockage is present. The difference between the inlet temperature and the observed outlet temperature is a function of flow rate and blockage extent: the greater these two factors, the higher the outlet temperature and consequently, the lower the temperature drop.

THE HEAT-BALANCE MODEL FOR A PARTIALLY-BLOCKED PIPELINE

The base relations are summarized below (see Appendix C for details of development of the model).

1) Intermediate Heat-Balance Equation (see Eq. A-39 in Appendix)

$$\frac{T_{amb} - T_{m2}}{T_{amb} - T_{m1}} = \exp \left\{ \frac{-2\pi r_o L_p}{Q_{flow} \rho C_p \left(\frac{r_o}{h_i (r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \right\} \dots (39)$$

2) Intermediate Heat-Balance Equation (written for the blocked section of pipe)

$$\frac{T_{amb} - T_{m2}}{T_{amb} - T_{m1}} = \exp \left\{ \frac{-2\pi r_o L_B}{Q_{flow} \rho C_p \left(\frac{r_o}{h_i (r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \right\} \dots (40)$$

3) Intermediate Heat-Balance Equation (written for the unblocked section of pipe)

$$\frac{T_{amb} - T_{m3}}{T_{amb} - T_{m2}} = \exp \left\{ \frac{-2\pi r_o (L_p - L_B)}{Q_{flow} \rho C_p \left(\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \right\} \dots (41)$$

4) Heat-Balance Model

$$\frac{T_{amb}-T_{mo}}{T_{amb}-T_{mi}} = \exp \left[\left(\frac{2\pi r_o L_p}{Q_{flow} \rho C_p \left(\frac{r_o}{hr_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} + \frac{2\pi r_o L_B}{Q_{flow} \rho C_p \left(\frac{1}{hr_B} + \frac{r_o}{k_w} \ln \frac{r_i}{r_B} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} + \frac{1}{hr_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \right) \right] \quad (42)$$

5) Final Heat-Balance Model for a Partially-Blocked Pipeline (expressed as a temperature drop)

$$T_{mi} - T_{mo} = T_{amb} [\exp(-Y) - 1] + T_{mi} [1 - \exp(-Y)] \dots\dots\dots (43)$$

$$\text{where } Y = \frac{2\pi r_o L_p}{Q_{flow} \rho C_p \left(\frac{r_o}{hr_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} + \frac{2\pi r_o L_B}{Q_{flow} \rho C_p \left(\frac{1}{hr_B} + \frac{r_o}{k_w} \ln \frac{r_i}{r_B} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} + \frac{1}{hr_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \quad (44)$$

TEMPERATURE SKIN FACTOR FOR A PARTIALLY-BLOCKED FLOWLINE

Eq. 42 is the heat model expression for a partially blocked pipe. For an unblocked pipe, $L_B = 0$ and Eq. 42 is simplified to Eq. 45.

$$\frac{T_{amb} - T_{mo}}{T_{amb} - T_{mi}} = \exp \left\{ - \left(\frac{2\pi r_o L_p}{Q_{flow} \rho C_p \left(\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \right) \right\} \dots \dots \dots (45)$$

Comparing Eqs. 42 and 45 reveals an extra term, which accounts for the blockage.

Again, this is the skin factor for a partial blockage in a flowline. It can be written as:

$$S = \frac{2\pi r_o L_B}{Q_{flow} \rho C_p} \left(\frac{1}{\frac{r_o}{h_i r_B} + \frac{r_o}{k_w} \ln \frac{r_i}{r_B} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} - \frac{1}{\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \right) \dots \dots \dots (46)$$

The heat model for a partially blocked pipe contains two unknowns, r_B and L_B . This model requires that either r_B or L_B be known either from the momentum- or the mass-balance approach; or the mass- or momentum-balance equation be solved simultaneously with the heat-balance equation for r_B and L_B .

The expression for skin factor reveals a direct relationship between the skin factor and the blockage length. The skin factor is observed to always be negative. The graphical results showing variations in parameters such as flow rate and blockage length for a partially-blocked pipeline are presented in **Figs. 7 through 18**.

Fig. 17—Temperature drop variation with dimensionless blockage radius and length ($6000 \text{ m}^3/\text{d}$).

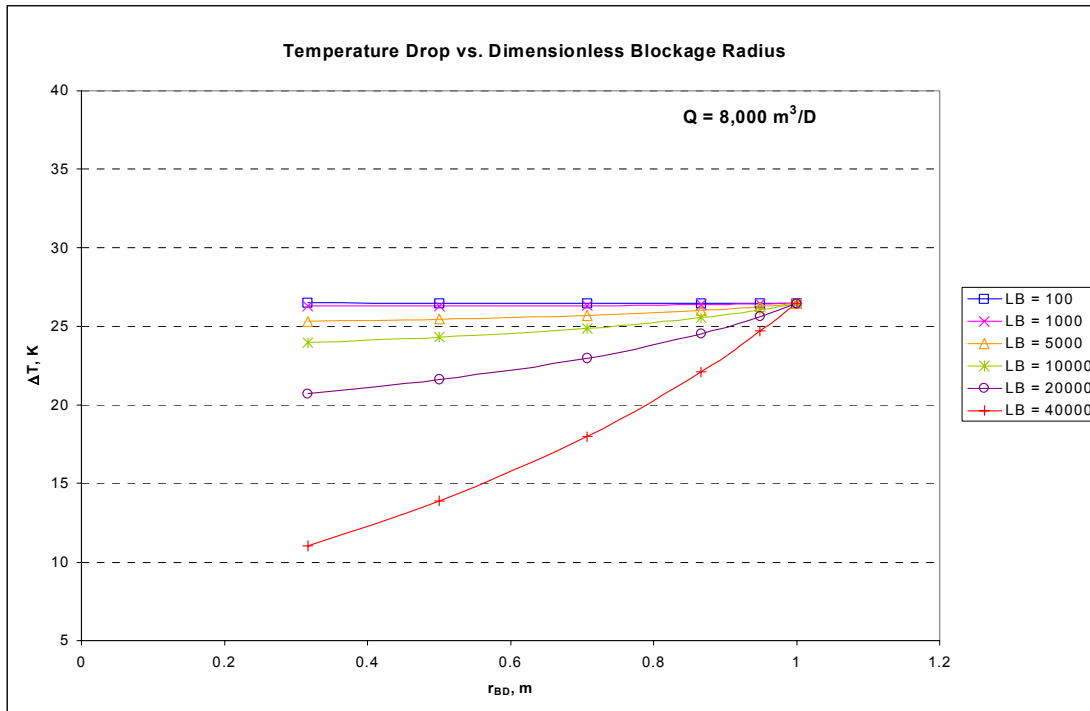

Fig. 18—Temperature drop variation with dimensionless blockage radius and length (8000 m³/d).

Discussion

The same insulating effect of the wax layer from the fully-blocked pipeline appears for the partially blocked pipeline; the greater the wax length, the lower the temperature drop from inlet to outlet, hence the greater the insulation. Also, the greater the flow rate, the less the temperature drop. At higher flow rates, the greater amount of fluid volume per unit pipe volume provides a greater surface area and heat capacity. The insulating effect observed at higher flow rates has less to do with the deposited wax and more to do with the greater heat content of the fluid.

At low flow rates and for 'short' blockages (0-20,000m), the effect of dimensionless blockage radius, in other words, the cross-sectional area available for flow, on temperature drop cannot be detected. Only extremely long blockages (40,000 m) show a variation in temperature drop with blockage radius. As flow rate increases, the effect of blockage radius on temperature drop for shorter blockages becomes more apparent.

THE DIMENSIONLESS HEAT-BALANCE MODEL FOR A PARTIALLY-BLOCKED PIPE

The base relations are summarized below (see Appendix E for details of development).

1) The Dimensionless Heat-Balance Model for a Partially-Blocked Pipe

$$T_D = \left[\exp\left(-\frac{2\pi L_p}{Q_{\text{flow}} \rho C_p} F_{TB}\right) - 1 \right] + \frac{T_{mi}}{T_{amb}} \left[1 - \exp\left(-\frac{2\pi L_p}{Q_{\text{flow}} \rho C_p} F_{TB}\right) \right] \dots\dots\dots (47)$$

2) The Dimensionless Temperature-Based Blockage Factor (F_{TB})

$$F_{TB} = \left[\frac{L_{BD}}{\frac{1}{h_i r_i r_{BD}} + \frac{1}{k_w} \ln \frac{1}{r_{BD}} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} + \frac{1}{\frac{1}{h_i r_i} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} - \frac{L_{BD}}{\frac{1}{h_i r_i} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} \right] \dots\dots\dots (48)$$

The dimensionless temperature drop factor (F_{TB}) also called the dimensionless temperature-based blockage factor defined in Eq. 48 has three unknowns: r_{BD} , L_{BD} and T_D . Two of these unknowns must be determined from the mass- and momentum-balance equations or experimentally for Eq. 48 to be useful. An example of the usefulness of F_{TB} is shown by a graphical solution of the heat- and momentum-balance models for an arbitrary case in **Fig. 19**. Graphical plots of equations 47 and 48 for certain values of flow rate and blockage radii are also presented in **Figs. 20 through 25**.

GRAPHICAL SOLUTION OF HEAT- AND VOLUME-BALANCE MODELS

Suppose we consider an average flow rate of $8000 \text{ m}^3/\text{d}$ of crude oil with properties as summarized in Table 2 flowing through the same North Sea pipeline described in Table 1. If F_{VB} is determined to be 0.75 from volumetric tests and F_{TB} is calculated as 0.2 from Eq. 48 using temperature measurements and fluid properties, the graphical solution of the volume-balance and heat-balance equations is shown in Fig. 19. There is a unique solution of blockage parameters that satisfy both models; they are $L_B = 13,760\text{m}$ and $D_B = 0.1672\text{m}$ (equivalent to 77% cross-sectional blockage).

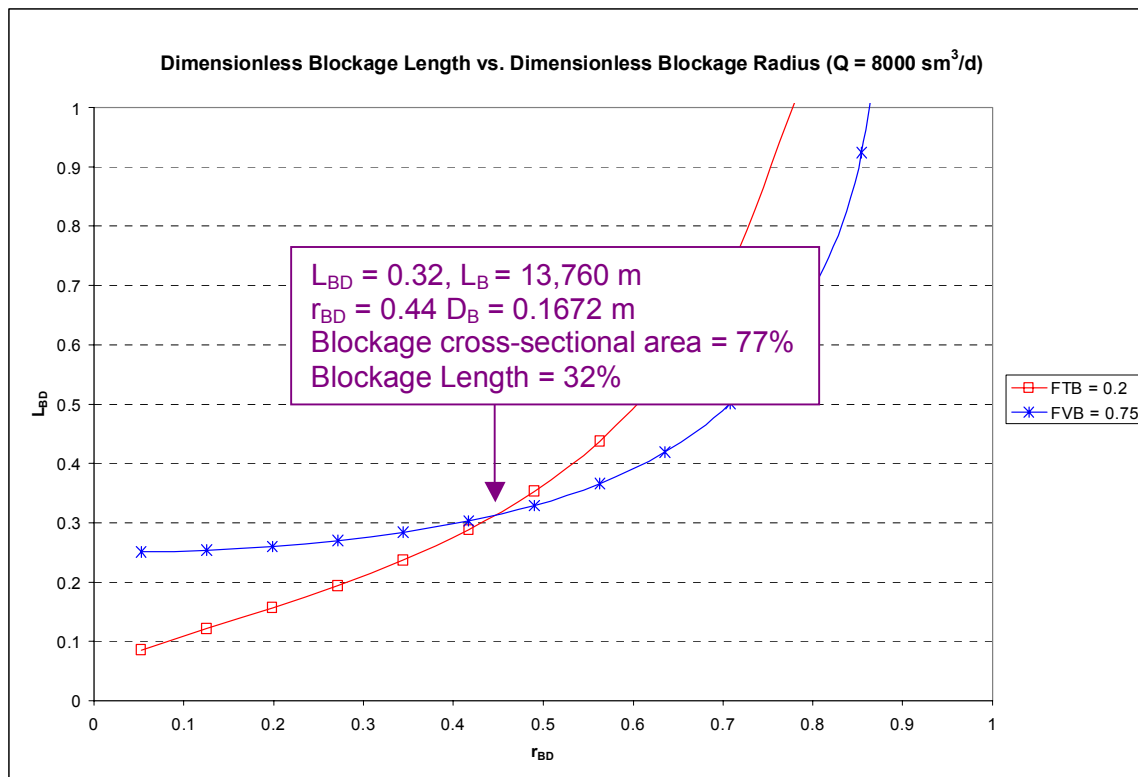

Fig. 19—Graphical solution of heat- and volume-balance models for blockage characterization of an arbitrary case.

DIMENSIONLESS TEMPERATURE DROP BLOCKAGE MAPS

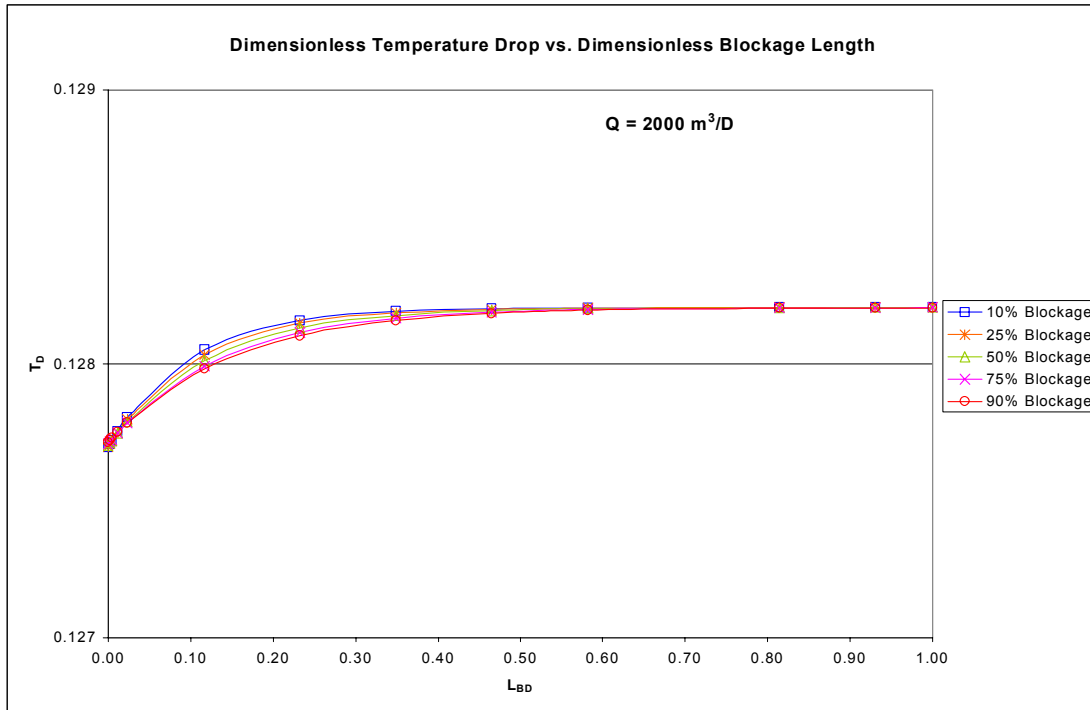

Fig. 20–Dimensionless temperature drop blockage map ($2000 \text{ m}^3/\text{d}$).

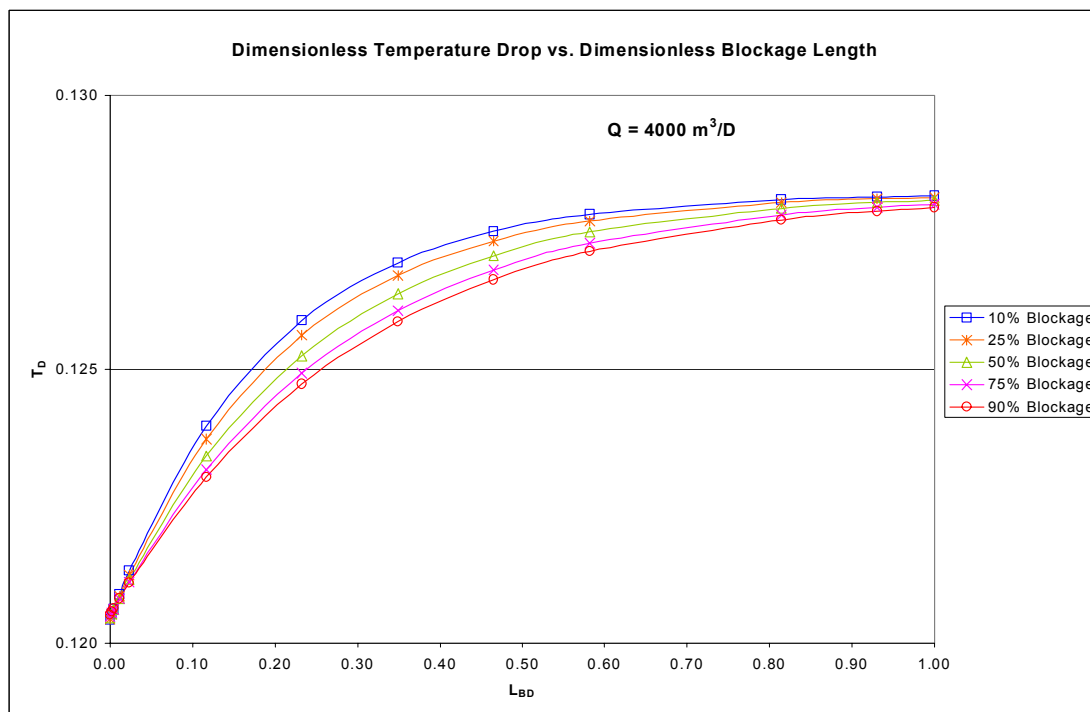

Fig. 21–Dimensionless temperature drop blockage map ($4000 \text{ m}^3/\text{d}$).

Fig. 22–Dimensionless temperature drop blockage map ($8000 \text{ m}^3/\text{d}$).

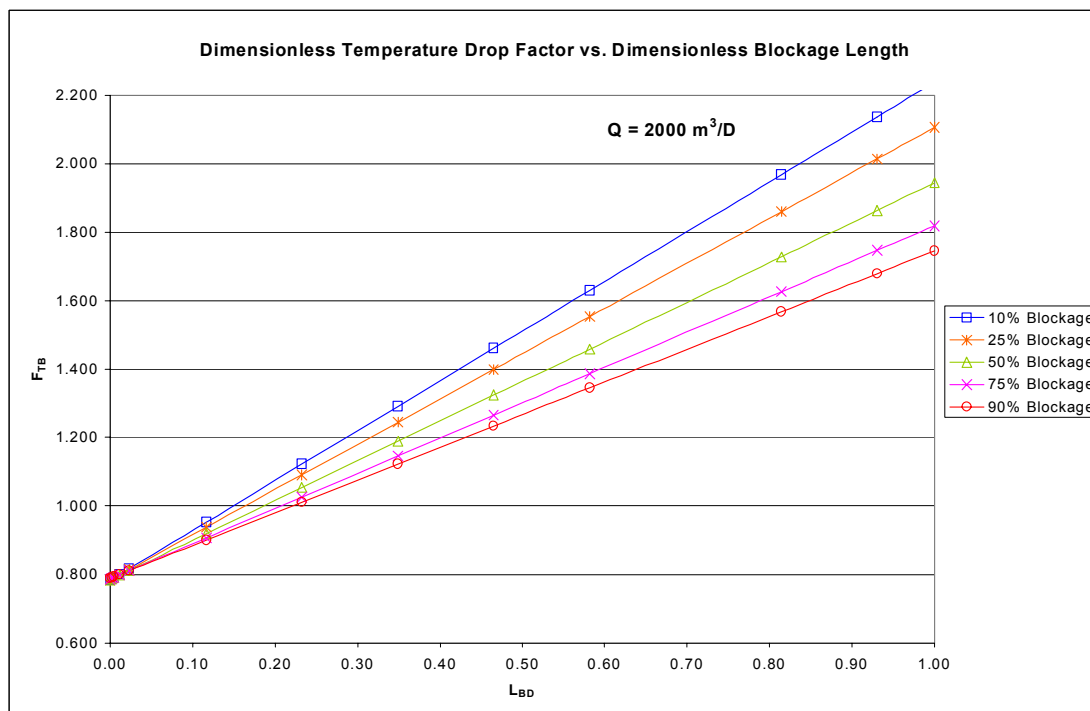

Fig. 23–Dimensionless temperature drop factor blockage map ($2000 \text{ m}^3/\text{d}$).

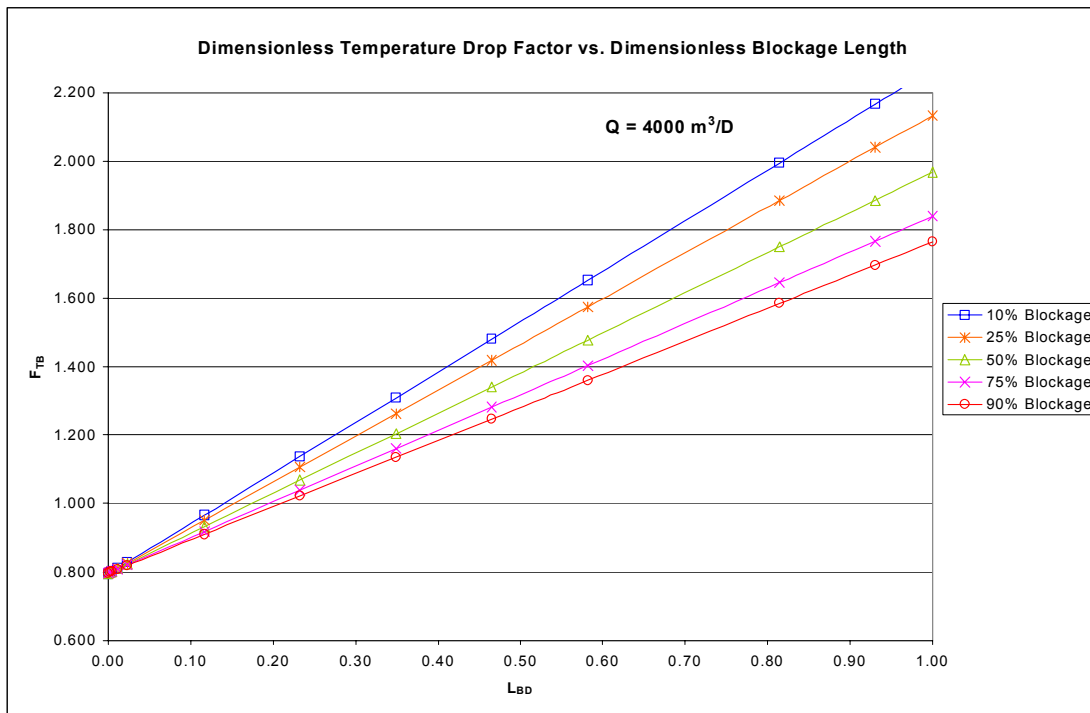

Fig. 24– Dimensionless temperature drop factor blockage map ($4000 \text{ m}^3/\text{d}$).

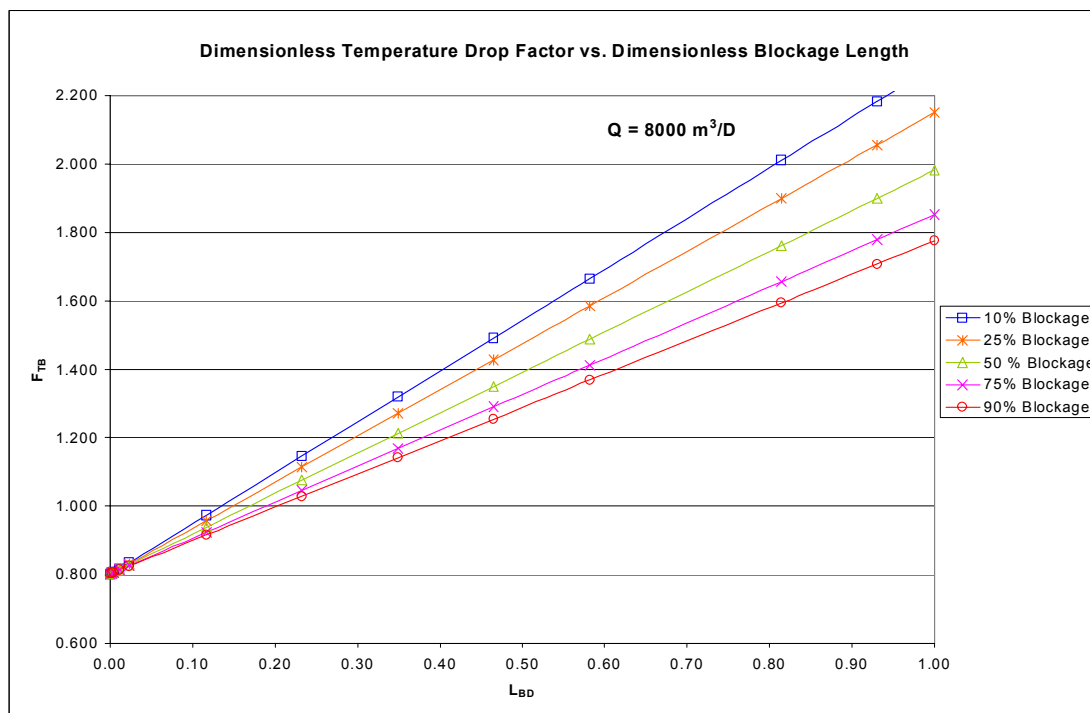

Fig. 25– Dimensionless temperature drop factor blockage map ($8000 \text{ m}^3/\text{d}$).

Discussion

The usefulness of these blockage maps comes in when armed with either the dimensionless blockage radius r_{BD} or dimensionless blockage length L_{BD} from other approaches and the average flow rate of the operational pipeline. This is illustrated in Fig. 19, which shows the graphical solution of F_{TB} and F_{VB} to determine the blockage parameters; L_B and r_B .

The dimensionless temperature drop maps show increased sensitivity of T_D to L_{BD} as flow rate increases while the dimensionless temperature drop factor maps F_{TB} essentially appear the same for all flow rates but have subtle differences in the actual values used to generate the plots.

Note:

$$r_{BD} = \sqrt{1 - \left(\frac{B}{100}\right)}$$

where $B = \text{Blockage, \%}$.

UNCERTAINTY IN BLOCKAGE CHARACTERIZATION

There is some uncertainty associated with the temperature measurements and all the other measured physical properties of the system. The uncertainty is related to the detectable blockage characteristics such as blockage length and diameter and therefore requires some investigation.

An arbitrary case of $F_{TB} = 2.2$ and $F_{VB} = 0.75$ is chosen. **Fig. 26** is a blockage map depicting the effect of uncertainty on temperature-based (F_{TB}) and volume-based factors (F_{VB}). **Figs. 27** through **29** depict the variation in dimensionless blockage length with dimensionless blockage radius as well as the graphical solution of blockage parameters for the cases of a 10%, 25% and 50% uncertainty in F_{TB} and F_{VB} for the case chosen.

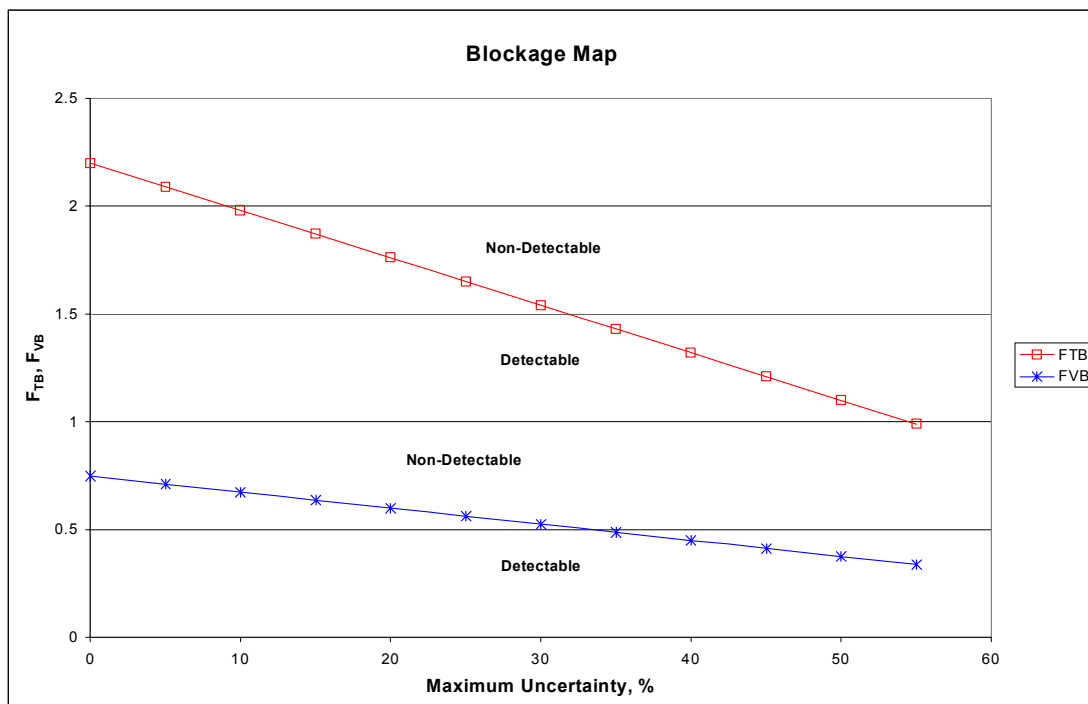

Fig. 26—Blockage map showing detectable blockage regions.

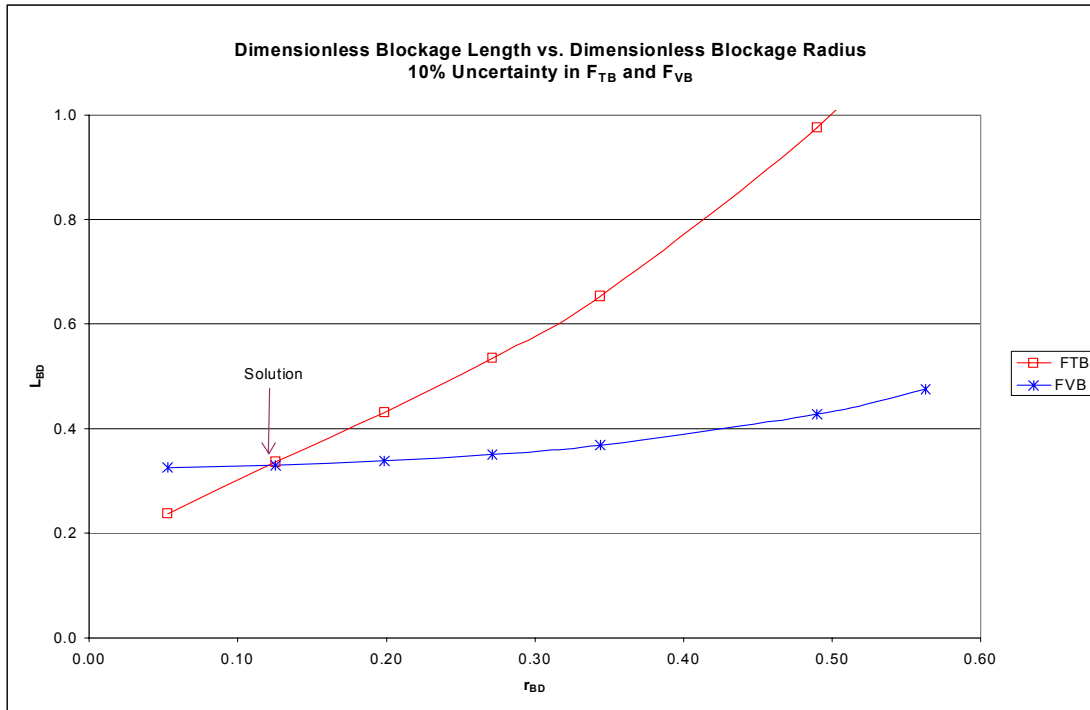

Fig. 27—Graphical solution of heat- and volume-balance models for blockage characterization incorporating 10% uncertainty.

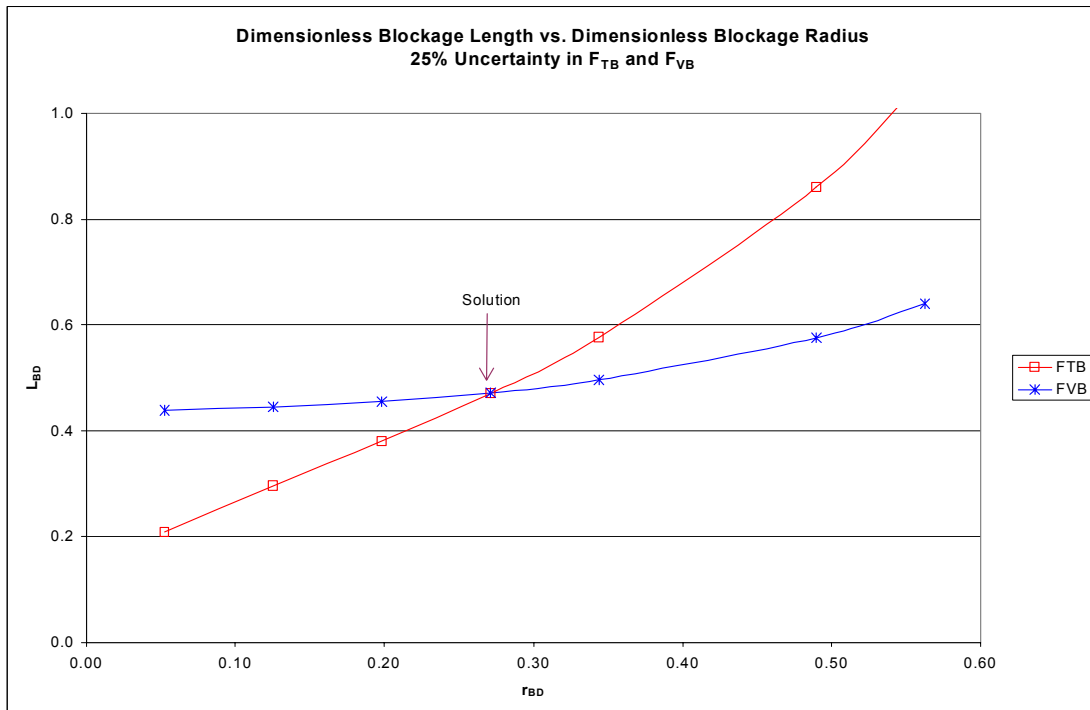

Fig. 28—Graphical solution of heat- and volume-balance models for blockage characterization incorporating 25% uncertainty.

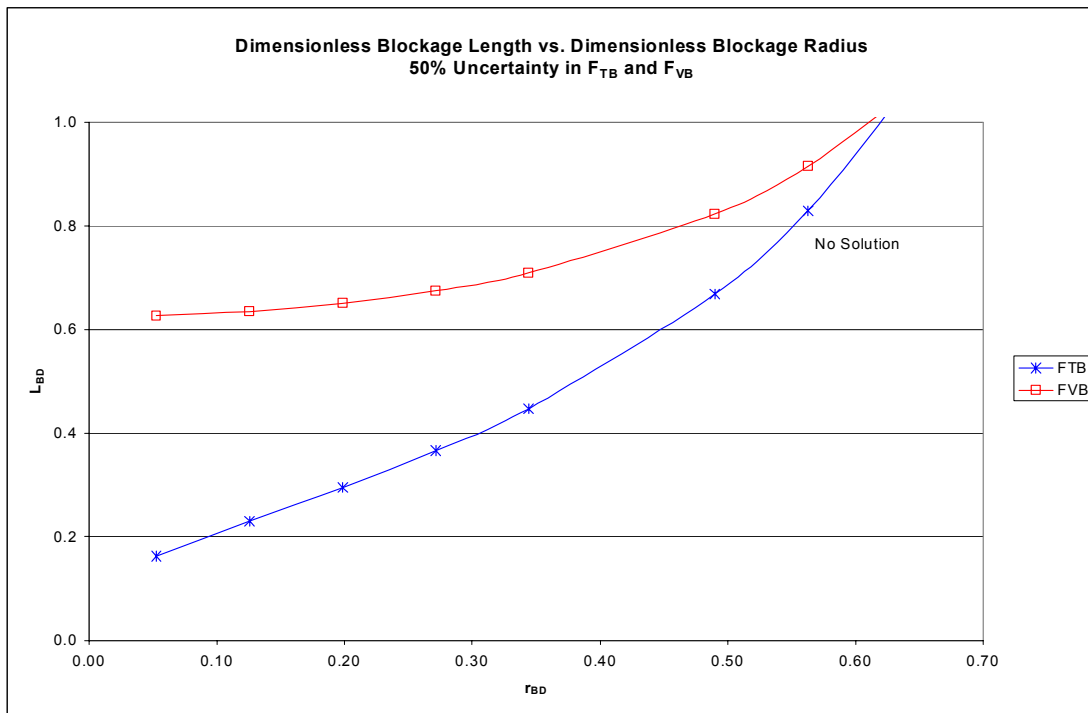

Fig. 29—Graphical plot of heat- and volume-balance models for blockage characterization incorporating 50% uncertainty. (No solution)

Discussion

The blockage map in Fig. 26 shows the ranges of F_{TB} and F_{VB} for an arbitrary case where the blockage can be detected assuming some level of uncertainty in the measurements of the physical properties of the system. Figs. 27 through 29 show that the possibility of characterizing a blockage by obtaining solutions of blockage parameters decreases with increasing uncertainty.

MODEL VERIFICATION

The model requires experimental verification, but because no facilities were available for this, the verification was restricted to the use of PIPESIM, a pipeline simulation software with inherent limitations that require that caution be exercised when making comparisons between its results and those from the model developed.

PIPESIM VERIFICATION

The pipeline was built with a source supplying the inlet temperature and pressure at one end and a boundary node at the other end, which provides the unknown outlet temperature used to calculate the temperature drop across the pipe.

Fig. 30—PIPESIM network built for comparison of results with heat model.

PIPESIM INPUT DATA

The input data into PIPESIM is summarized in **Tables 3 and 4**.

Table 3–Pipeline Input Data to PIPESIM

Inlet Pressure	5000 psia
Inlet Temperature	35 °C
Pipe length	43 km
Inner Diameter	0.38 m
Outer Diameter	0.4054 m
Ambient Temperature	0 °C
Pipe Thermal Conductivity	43.25 W/mK

Table 4–Fluid Input Data to PIPESIM

GOR	300 scf/STB
API	30
Wax Thermal Conductivity	0.25 W/mK

The wax deposition module in PIPESIM, a separate module requiring BP or Shell security is unavailable for unlicensed users. This problem was circumvented by using the “detailed pipeline description” to model the wax layer as a coating of insulation, but with the thermal conductivity of the wax.

GRAPHICAL COMPARISON OF PIPESIM AND MODEL PREDICTIONS

The wax thickness was varied and the simulation was run for various inlet-pressure and flow-rate combinations. The software was unable to simulate certain combinations of blockage and flow conditions, most likely because the pressure was insufficient for the prescribed flow rate. The results are presented as **Figs. 31 through 53**.

Fig. 53—Comparison of temperature drop variation with flow rate predicted by PIPESIM and Model (Wax Thickness = 0.09 m).

Discussion of Results

Overall, the match between the PIPESIM and model predictions is good. However, for all conditions of wax thickness and flow rate, the actual temperature drop simulated by PIPESIM is consistently lower than the temperature drop predicted by the model. This implies that the model is actually under-predicting the insulating effect of the wax layer.

There are two distinct regions where the match is poor: the first one is at low flow rates and thin layers of wax deposited and the second is at high flow rates and thick wax layers. For the first region, the PIPESIM prediction shows an overall inconsistent trend, which the model fails to match. At very low flow rates, (implying very low thermal masses) and without the benefit of the effect of pressure as modeled by PIPESIM, the model predicts a complete loss of heat energy coming into the pipe. The model does not take into account the effect of inlet pressure; and this, combined with the low thermal mass flowing in a very long pipeline results in a complete loss of heat energy into the system; to the extent that the insulating effect of the wax becomes negligible and the discrepancy between the temperature drop predicted by the model and PIPESIM is much wider in this region. This seems to indicate that for a given pipeline system, there is a minimum thermal heat content input required for accurate comparison of temperature drop predictions.

For the second region, the increasing wax thicknesses imply a reduction in effective cross-sectional area for flow; and this, combined with increasing flow rates results in

increased frictional heating, which the model fails to capture, making it predict higher temperature drops than PIPESIM. The dynamic PIPESIM simulation takes into account parameters such as pressure and friction factor, which are able to model this effect. The model does not incorporate these factors and this may be one of the major causes of the discrepancy between the results at the second extreme condition.

Clearly, there may be regions of flow and blockage conditions for which the model is inapplicable. These regions of inapplicability must be investigated to determine the limits of the model and ensure its robustness. This model might require tuning, like an equation of state, for the unique conditions of the operational pipeline, to improve its ability to accurately reproduce the expected temperature drop for a given layer of deposited wax.

The approach used here of adding the wax layer as a coating may also be a limitation. Investigating the model using an actual wax deposition module that incorporates the mechanisms of wax deposition such as diffusion and shear dispersion would provide simulated results that are more representative of wax deposition conditions in a pipeline, and help assess and improve the accuracy of the model predictions.

CONCLUSIONS

- 1) The heat model developed here is theoretically consistent. It correctly predicts the insulating effect of wax deposited in a pipeline by relating the thickness of wax deposited to the observed temperature drop, which is consistently lower than the temperature drop that would result if no wax blockage were present.
- 2) A temperature-based factor (F_{TB}) similar to the volume-based factor (F_{VB}) and friction-based factor (F_{FB}) was developed and correlated to blockage length and effective pipe diameter for a partially blocked pipeline. Dimensionless blockage maps developed here for unique flow conditions require knowledge of at least two of the three unknown variables (dimensionless blockage radius, length and temperature drop) to determine the third variable.
- 3) A back-temperature plot is developed similar to a backpressure plot but with a negative slope. The effect of a uniform blockage can be seen on a back-temperature plot as a shift in trend below the zero-blockage line (for the baseline case). The greater the blockage, the greater the departure from the zero-blockage line.
- 4) The overall reduction in temperature drop from pipe inlet to outlet is actually the result of the combined effect of the insulation from the wax layer and the flow rates. It is observed that for a fixed blockage, the temperature drop from pipe inlet to outlet decreases with increasing flow rate. This is because higher flow rates imply greater volumes of fluid, higher heat contents (mC_p), a greater overall retention of heat in the system and a lower temperature drop from inlet to outlet.

- 5) A skin factor is developed as the extra term in the denominator of the overall heat transfer coefficient for a blocked pipeline. The skin factor accounts for the insulating effect of the blockage and has an inverse relationship to the temperature drop from pipe inlet to outlet.
- 6) It is also noted that the temperature drop is more sensitive to skin factor or the effects of blockage at higher flow rates than at lower flow rates. At low flow rates and for 'short' blockages (0-20,000 m), the effect of blockage radius (the cross-sectional area available for flow) on temperature drop cannot be detected. Only extremely long blockages (40,000 m) show a variation in temperature drop with blockage radius. As flow rate increases, the effect of blockage radius on temperature drop for shorter blockages becomes more apparent.
- 7) Overall, there is a good match between the temperature drop predictions from the model and PIPESIM simulation. The results from the model are consistently lower than the PIPESIM predictions indicating that the model is under-estimating the insulating effect of the deposited wax.
- 8) It is also noted the match between the model and PIPESIM seems to be optimal for certain regions of flow conditions, possibly indicating that the model has regions of applicability that must be further investigated.
- 9) There appear to be two distinct regions where the match between the model and PIPESIM is poor: the first one is at low flow rates and thin layers of wax deposited and the second is at high flow rates and thick wax layers. Low flow rates imply low thermal heat content into the system, which for extensive pipeline lengths, result in a

complete loss of heat energy, if inlet pressure is unaccounted for. The difference between the temperature drop predictions by PIPESIM and the model is that PIPESIM, unlike the model, incorporates inlet pressure, which provides a 'pressure boost' minimizing temperature drop along the pipeline. This results in PIPESIM predicting temperature drops that are consistently lower than the model predictions in this region.

For the second region, the combination of high flow rates and high wax thickness result in increased frictional heating, accounted for by the PIPESIM simulation, but unaccounted for in the model. The increased frictional heating results in a lower system heat loss and a lower temperature drop prediction by PIPESIM.

RECOMMENDATIONS

- 1) Improvement of the accuracy of the model may be achieved by investigating and incorporating the effects of:
 - a. Variation of fluid physical properties (such as μ and ρ) with temperature and pressure,
 - b. Friction on temperature drop for severely restricted pipes,
 - c. Sensitivity of the model to the internal convective heat transfer coefficient (h_i).
The Dittus-Boelter correlation used in this study is noted to have errors as large as 25%.
- 2) The model requires rigorous investigation to determine its regions of validity. The ideal approach would be experimental validation.
- 3) The model needs to be extended to multiphase flow.
- 4) In the absence of experimental validation, a license for the Wax Deposition module of PIPESIM should be sought to enable a more realistic simulation of wax deposition, to enable validation of this model.
- 5) The possibility of becoming part of the Joint Industry Project on Paraffin Deposition Prediction in Multiphase Flowlines and Wellbores headed by the University of Tulsa should be explored. This would enable access to the large resources of information already available.

PROPOSED EXTENSION TO MULTIPHASE FLOW

The model has been developed for single phase flow applications but requires extension to multiphase flowing conditions to gain widespread relevance and usefulness. The multiple phases would affect the internal convective heat transfer coefficient (h_i). The 2-phase internal convective heat transfer coefficient ($h_i^{2-\phi}$) would be a function of the flow regime and liquid hold-up. The h_i for each phase would need to be determined from correlations; and weighted by the liquid hold-up (such as density, viscosity and other 2-phase properties) to obtain the two-phase internal convective heat transfer ($h_i^{2-\phi}$).

NOMENCLATURE

T_{amb}	=	Ambient air or sea temperature
B	=	Blockage (%)

APPENDIX A

DEVELOPMENT OF THE HEAT-BALANCE MODEL FOR A

FULLY-BLOCKED PIPELINE

Consider **Fig. A-1** depicting a pipeline of length L_p blocked along its entire length such that $L_B = L_p$. The fluid flowing internally has the properties shown below and the pipeline is exposed to ambient air conditions.

Fig. A-1—Schematic of a pipeline fully-blocked along its entire length.

Assumptions

- 1) Single-phase liquid.
- 2) Steady-state conditions.
- 3) Pipe of uniform radial geometry.
- 4) Wax thickness uniform over entire length of pipe.
- 5) Non-adiabatic system.

Taking a heat balance;

$$\Delta Q = Q_{in} - Q_{out} \dots\dots\dots (A-1)$$

where ΔQ is the change in heat energy, Q_{in} the heat energy entering the pipe, and Q_{out} the heat energy leaving the pipe.

The change in heat energy is predominantly made up of heat losses from conduction, convection and radiation. The expressions for each component of the heat loss from the system can now be evaluated independently.

For now, let's take a unit volume element of the pipe and assume that the bulk fluid temperature is uniform and equal to T_m . (Note the wax thickness is δ_w).

The system above could be reduced to an equivalent electrical circuit:

Fig. A-2—Illustration of thermal circuit represented as equivalent electrical circuit.

The heat energy across the unit volume element is made up of 4 components;

- 1) Q_1 – internal convection (from the fluid).
- 2) Q_2 – conduction through the wax layer.
- 3) Q_3 – conduction through the pipe wall.
- 4) Q_4 – external convection (to the ambient air).

We note that:

$$Q_{out} = Q = Q_1 = Q_2 = Q_3 = Q_4 \dots \dots \dots (A-2)$$

For a radial system,

The convective heat component is given by Eq. A-3,

$$Q = hA\Delta T \dots \dots \dots (A-3)$$

and Eq. A-4 gives the conductive heat component.

$$Q = kA \frac{dT}{dr} = \frac{2\pi Lk\Delta T}{\ln\left(\frac{r_o}{r_i}\right)} \dots \dots \dots (A-4)$$

The overall temperature gradient from the pipe inlet to the ambient conditions is given by:

$$T_{amb} - T_{mi} = (T_i - Ts_1) + (Ts_1 - Ts_2) + (Ts_2 - Ts_3) + (Ts_3 - T_{amb}) \dots \text{(A-5)}$$

Each temperature gradient may be expressed in terms of a resistance.

$$\Delta T = \frac{Q}{R} \dots \dots \dots \text{(A-6)}$$

Eq. A-5 can then be expressed as Eq. A-7:

$$\Delta T = T_{amb} - T_{mi} = \frac{Q}{R_{tot}} = \frac{Q}{h_i A} + \frac{Q \ln\left(\frac{r_i}{r_i - \partial_w}\right)}{2\pi L k_w} + \frac{Q \ln\left(\frac{r_o}{r_i}\right)}{2\pi L k_p} + \frac{Q}{h_o A} \text{(A-7)}$$

This can be further simplified to Eq. A-8:

$$T_{amb} - T_{mi} = Q \left[\frac{1}{h_i A} + \frac{\ln\left(\frac{r_i}{r_i - \partial_w}\right)}{2\pi L k_w} + \frac{\ln\left(\frac{r_o}{r_i}\right)}{2\pi L k_p} + \frac{1}{h_o A} \right] \dots \dots \dots \text{(A-8)}$$

$$Q = \frac{T_{amb} - T_{mi}}{\frac{1}{h_i A_i} + \frac{\ln\left(\frac{r_i}{r_i - \partial_w}\right)}{2\pi L k_w} + \frac{\ln\left(\frac{r_o}{r_i}\right)}{2\pi L k_p} + \frac{1}{h_o A_o}} \quad \text{..... (A-9)}$$

Eq. A-9 is the general expression for the heat loss from a unit volume element of pipe with a fluid flowing through it. It can be further simplified by substituting the expressions for the internal and external surface areas.

$$A_o = 2\pi r_o L_p \quad \text{..... (A-10)}$$

$$A_i = 2\pi r_i L_p \quad \text{..... (A-11)}$$

Eq. A-9 becomes:

$$Q = \frac{T_{amb} - T_{mi}}{\frac{1}{2\pi(r_i - \partial_w)L_p h_i} + \frac{\ln\left(\frac{r_i}{r_i - \partial_w}\right)}{2\pi L k_w} + \frac{\ln\left(\frac{r_o}{r_i}\right)}{2\pi L k_p} + \frac{1}{2\pi r_o L_p h_o}} \quad \text{(A-12)}$$

Basing the heat flow on the external area of the pipe yields:

$$Q = q'' A = 2\pi r_o L_p q'' , \dots\dots\dots (A-13)$$

where q'' is the heat flux (heat flow per unit area).

Substituting equation (A-13) into (A-12) yields:

$$2\pi r_o L_p q'' = \frac{T_{amb} - T_{mi}}{\frac{1}{2\pi(r_i - \partial_w)L_p h_i} + \frac{\ln\left(\frac{r_i}{r_i - \partial_w}\right)}{2\pi L k_w} + \frac{\ln\left(\frac{r_o}{r_i}\right)}{2\pi L k_p} + \frac{1}{2\pi r_o L_p h_o}} \quad (A-14)$$

$$q'' = \frac{T_{amb} - T_{mi}}{\frac{r_o}{h_i(r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \quad \dots\dots\dots (A-15)$$

Eq. A-15 is the final expression for the heat flux from a unit volume element of pipe. However, we know that the temperature of the fluid will vary from inlet to outlet over the entire pipeline; and it is this gradient ($T_{mi} - T_{mo}$) that we are interested in, so we need to do some further manipulation:

We can rewrite Eq. A-15 in general terms as:

$$Q = UA \Delta T \dots\dots\dots (A-16)$$

$$UA = \frac{Q}{\Delta T} = \frac{1}{R} = \frac{1}{\frac{1}{2\pi(r_i - \partial_w)L_p h_i} + \frac{\ln\left(\frac{r_i}{r_i - \partial_w}\right)}{2\pi L k_w} + \frac{\ln\left(\frac{r_o}{r_i}\right)}{2\pi L k_p} + \frac{1}{2\pi r_o L_p h_o}} \quad (A-17)$$

where U is the overall heat transfer coefficient and;

$$\Delta T = T_{amb} - T_{mi} \dots\dots\dots (A-18)$$

For the entire pipe, the overall heat input is given by:

$$Q_{in} = q = \dot{m} C_p dT_m \dots\dots\dots (A-19)$$

Therefore,

$$\dot{m} C_p dT_m = q'' A = UA \Delta T = U(P dx) \Delta T, \dots\dots\dots (A-20)$$

where P is the perimeter of the pipe.

$$dT_m = T_{mi} - T_{mo} \equiv -[(T_{amb} - T_{mi}) - (T_{amb} - T_{mo})] = -d(\Delta T) \dots (A-21)$$

From Eq. A-20;

$$\frac{dT_m}{dx} = \frac{-d(\Delta T)}{dx} = \frac{P}{\dot{m}C_p} U \Delta T \dots\dots\dots (A-22)$$

Separating variables and integrating from inlet to outlet yields:

$$\int_{\Delta T_i}^{\Delta T_o} \frac{-d(\Delta T)}{\Delta T} = \int_0^{L_p} \frac{P}{\dot{m}C_p} U dx \dots\dots\dots (A-23)$$

$$\ln \frac{\Delta T_o}{\Delta T_i} = -\frac{PL_p}{\dot{m}C_p} \bar{U} = -\frac{\bar{U}A}{\dot{m}C_p} \dots\dots\dots (A-24)$$

$$\dot{m}C_p = -\frac{\bar{U}A}{\ln \frac{\Delta T_i}{\Delta T_o}} \dots\dots\dots (A-25)$$

Multiplying both sides by $(\Delta T_o - \Delta T_i)$ yields:

$$Q = \dot{m}C_p (\Delta T_o - \Delta T_i) = -\bar{U}A \frac{\Delta T_o - \Delta T_i}{\ln \frac{\Delta T_o}{\Delta T_i}} \equiv -\bar{U}A_s \Delta T_{lm} , \dots\dots\dots (A-26)$$

$$\Delta T_{lm} = \frac{\Delta T_o - \Delta T_i}{\ln \frac{\Delta T_o}{\Delta T_i}}, \dots\dots\dots (A-27)$$

where \bar{U} is the overall heat transfer coefficient and ΔT_{lm} the logarithmic mean temperature difference.

Basing the overall heat transfer coefficient on the outside surface area,

$$A_o = 2\pi r_o L_p \dots\dots\dots (A-28)$$

$$\bar{U}_o = \bar{U} A_o = 2\pi r_o L_p \bar{U} \dots\dots\dots (A-29)$$

where \bar{U}_o is the overall heat transfer coefficient based on the external surface area.

Equating Eqs. A-17 and A-29,

$$2\pi r_o L_p \bar{U} = \frac{1}{\frac{1}{2\pi(r_i - \partial_w)L_p h_i} + \frac{\ln\left(\frac{r_i}{r_i - \partial_w}\right)}{2\pi L k_w} + \frac{\ln\left(\frac{r_o}{r_i}\right)}{2\pi L k_p} + \frac{1}{2\pi r_o L_p h_o}} \quad (A-30)$$

This simplifies to Eq. A-31:

$$\bar{U} = \frac{1}{\frac{r_o}{h_i(r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \dots\dots\dots (A-31)$$

Going back to Eq. A-26, the temperature gradients can be expanded as follows:

$$\Delta T_o = T_{amb} - T_{mo} \dots\dots\dots (A-32)$$

$$\Delta T_i = T_{amb} - T_{mi} \dots\dots\dots (A-33)$$

Substituting Eqs. A-32 and A-33 into A-26 yields:

$$Q = \dot{m} C_p (\Delta T_o - \Delta T_i) = \frac{-2\pi r_o L_p \left(\frac{(T_{amb} - T_{mo}) - (T_{amb} - T_{mi})}{\ln \frac{T_{amb} - T_{mo}}{T_{amb} - T_{mi}}} \right)}{\frac{r_o}{h_i(r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \dots\dots\dots (A-34)$$

Defining the mass flow rate,

$$\dot{m} = \rho Q_{flow} \dots\dots\dots (A-35)$$

The pipe wall resistance, though negligible when compared to the other resistances because its thermal conductivity (k_p) tends to infinity, is included in all calculations.

$$Q = \rho Q_{\text{flow}} C_p (T_{mi} - T_{mo}) = \left[\frac{-2\pi r_o L_p \left(\frac{(T_{\text{amb}} - T_{mo}) - (T_{\text{amb}} - T_{mi})}{\ln \frac{T_{\text{amb}} - T_{mo}}{T_{\text{amb}} - T_{mi}}} \right)}{\frac{r_o}{h_i(r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \right] \quad (\text{A-36})$$

$$Q_{\text{flow}} = \left[\frac{-2\pi r_o L_p \left(\frac{(T_{mi} - T_{mo})}{\ln \frac{T_{\text{amb}} - T_{mo}}{T_{\text{amb}} - T_{mi}}} \right)}{\left(\frac{r_o}{h_i(r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right) \rho C_p (T_{mi} - T_{mo})} \right] \quad (\text{A-37})$$

$$Q_{\text{flow}} = \left[\frac{-2\pi r_o L_p}{\rho C_p \ln \left(\frac{T_{\text{amb}} - T_{mo}}{T_{\text{amb}} - T_{mi}} \right) \left(\frac{r_o}{h_i(r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \right] \quad (\text{A-38})$$

$$\frac{T_{amb} - T_{mo}}{T_{amb} - T_{mi}} = \exp \left\{ \frac{-2\pi r_o L_p}{Q_{flow} \rho C_p \left(\frac{r_o}{h_i (r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \right\} \quad (\text{A-39})$$

Eq. A-39 can be expressed simply as:

$$\frac{T_{amb} - T_{mo}}{T_{amb} - T_{mi}} = \exp \left\{ \frac{-\bar{U} A_o}{Q_{flow} \rho C_p} \right\} \dots \dots \dots (\text{A-40})$$

where;

$$\bar{U} = \frac{1}{\frac{r_o}{h_i (r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \dots \dots \dots (\text{A-41})$$

$A_o = 2\pi r_o L_p$, is based on the pipe external surface area and C_p is the specific heat capacity of the oil.

Eq. A-41 can be further manipulated to yield a temperature drop:

$$T_{amb} - T_{mo} = T_{amb} \exp \left\{ \frac{-\bar{U} A_o}{Q_{flow} \rho C_p} \right\} - T_{mi} \exp \left\{ \frac{-\bar{U} A_o}{Q_{flow} \rho C_p} \right\} \dots \dots \dots (\text{A-42})$$

$$T_{mi} - T_{mo} = T_{mi} - T_{amb} + T_{amb} \exp\left\{\frac{-\bar{U}A_o}{Q_{\text{flow}}\rho C_p}\right\} - T_{mi} \exp\left\{\frac{-\bar{U}A_o}{Q_{\text{flow}}\rho C_p}\right\} \dots\dots (A-43)$$

Eq. A-44 gives the final heat-balance model for a fully-blocked pipeline.

$$T_{mi} - T_{mo} = T_{amb} \left[\exp\left\{\frac{-\bar{U}A_o}{Q_{\text{flow}}\rho C_p}\right\} - 1 \right] + T_{mi} \left[1 - \exp\left\{\frac{-\bar{U}A_o}{Q_{\text{flow}}\rho C_p}\right\} \right] \dots\dots\dots (A-44)$$

APPENDIX B**EXCEL SPREADSHEET FOR THE HEAT-BALANCE MODEL FOR
A FULLY-BLOCKED PIPELINE AND DATA FOR FIGS. 3 AND 6**

Heat Transfer Approach to Blockage Detection
Blocked Pipe (Uniform blockage over entire length of pipe)

APPENDIX C

DEVELOPMENT OF THE HEAT-BALANCE MODEL FOR A

PIPELINE WITH A LOCALIZED BLOCKAGE

The model developed in the previous section was for a fully-blocked pipeline, i.e., a pipeline with a blockage along its entire length. In this section, a model is developed for the more common situation of a pipeline with a localized blockage.

Assumptions

- 1) Steady-state conditions
- 2) Constant surface temperature along the length of the pipe.
- 3) Uniform wax thickness deposited radially over length L_B of the pipe.
- 4) Non-adiabatic system.

Fig. C-1 shows a pipeline with a localized radial blockage of length L_B at the pipe inlet. The fluid and wax properties are shown below and the pipeline is exposed to ambient air conditions.

Fig. C-1—Illustration of a pipeline with a localized blockage at pipe inlet.

Recalling Eq. A-39,

$$\frac{T_{amb} - T_{m0}}{T_{amb} - T_{mi}} = \exp \left\{ \frac{-2\pi r_o L_p}{Q_{flow} \rho C_p \left(\frac{r_o}{h_i (r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \right\} \quad (\text{A-39})$$

Eq. A-39 can be written for the two sections of the pipe— the blocked and unblocked lengths respectively, as follows:

$$\frac{T_{amb} - T_{m2}}{T_{amb} - T_{m1}} = \exp \left\{ \frac{-2\pi r_o L_B}{Q_{flow} \rho C_p \left(\frac{r_o}{h_i (r_i - \partial_w)} + \frac{r_o}{k_w} \ln \frac{r_i}{r_i - \partial_w} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \right\} \quad \dots (\text{C-1})$$

$$\frac{T_{amb} - T_{m3}}{T_{amb} - T_{m2}} = \exp \left\{ \frac{-2\pi r_o (L_p - L_B)}{Q_{flow} \rho C_p \left(\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \right\} \dots (\text{C-2})$$

Setting $r_B = r_i - \delta_\omega$ and combining the above equations into Eq. C-4:

$$\frac{T_{amb} - T_{m2}}{T_{amb} - T_{m1}} \times \frac{T_{amb} - T_{m3}}{T_{amb} - T_{m2}} = \exp \left\{ \left(\frac{2\pi_o L_B}{Q_{flow} \mathcal{C}_p \left(\frac{r_o}{h_i r_B} + \frac{r_o}{k_w} \ln \frac{r_i}{r_B} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} + \frac{2\pi_o (L_p - L_B)}{Q_{flow} \mathcal{C}_p \left(\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} \right) \right\} \quad (C-3)$$

$$\frac{T_{amb} - T_{m3}}{T_{amb} - T_{m1}} = \exp \left\{ \left(\frac{2\pi_o L_p}{Q_{flow} \mathcal{C}_p \left(\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} + \frac{2\pi_o L_B}{Q_{flow} \mathcal{C}_p} \left(\frac{1}{\frac{r_o}{h_i r_B} + \frac{r_o}{k_w} \ln \frac{r_i}{r_B} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} - \frac{1}{\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \right) \right) \right\} \quad (C-4)$$

(Note: $T_{m1} = T_{mi}$ and $T_{m3} = T_{mo}$)

Eq. C-5 is the final expression for the heat-balance model for a partially-blocked pipe.

$$\frac{T_{amb} - T_{mo}}{T_{amb} - T_{mi}} = \exp \left\{ \left(\frac{2\pi_o L_p}{Q_{flow} \mathcal{C}_p \left(\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} + \frac{2\pi_o L_B}{Q_{flow} \mathcal{C}_p} \left(\frac{1}{\frac{r_o}{h_i r_B} + \frac{r_o}{k_w} \ln \frac{r_i}{r_B} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} - \frac{1}{\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \right) \right) \right\} \quad (C-5)$$

Replacing the bracketed term by a variable, Y ; Eq. C-5 can be expressed as a temperature drop as in Eq. C-6.

$$T_{mi} - T_{mo} = T_{amb} [\exp(-Y) - 1] + T_{mi} [1 - \exp(-Y)] \dots\dots\dots (C-6)$$

$$\text{where } Y = \frac{2\pi r_o L_p}{Q_{\text{flow}} \rho C_p \left(\frac{r_o}{hr_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} + \frac{2\pi r_o L_B}{Q_{\text{flow}} \rho C_p} \left(\frac{1}{\frac{r_o}{hr_B} + \frac{r_o}{k_w} \ln \frac{r_i}{r_B} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} - \frac{1}{\frac{r_o}{hr_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \right)$$

(C-7)

APPENDIX E

DEVELOPMENT OF THE DIMENSIONLESS HEAT-BALANCE

MODEL FOR A PARTIALLY-BLOCKED PIPE

Recalling the original form of the heat model for a partially blocked pipe:

$$\frac{T_{amb}-T_{mo}}{T_{amb}-T_{mi}} = \exp \left\{ \left(\frac{2\pi_o L_p}{Q_{flow} \mathcal{C}_p \left(\frac{r_o}{hr_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} + \frac{2\pi_o L_B}{Q_{flow} \mathcal{C}_p \left(\frac{1}{hr_B} + \frac{r_o}{k_w} \ln \frac{r_i}{r_B} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} - \frac{1}{\frac{r_o}{hr_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \right) \right\} \quad (C-5)$$

Expressed as a temperature drop in Eq. E-1:

$$T_{mi} - T_{mo} = T_{amb} [\exp(-Y) - 1] + T_{mi} [1 - \exp(-Y)] \dots\dots\dots (E-1)$$

where $Y = \frac{2\pi_o L_p}{Q_{flow} \mathcal{C}_p \left(\frac{r_o}{hr_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} + \frac{2\pi_o L_B}{Q_{flow} \mathcal{C}_p \left(\frac{1}{hr_B} + \frac{r_o}{k_w} \ln \frac{r_i}{r_B} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o} \right)} - \frac{1}{\frac{r_o}{hr_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}}$ (E-2)

We define the following dimensionless terms and substitute them in Eqs. E-3 and E-4;

$$L_{BD} = \frac{L_B}{L_p} \dots\dots\dots (E-3)$$

$$r_{BD} = \frac{r_B}{r_i} \dots\dots\dots (E-4)$$

$$T_D = \frac{T_{mi} - T_{mo}}{T_{amb}} \dots\dots\dots (E-5)$$

$$T_D = \frac{T_{mi} - T_{mo}}{T_{amb}} = [\exp(-Y) - 1] + \frac{T_{mi}}{T_{amb}} [1 - \exp(-Y)] \dots\dots\dots (E-6)$$

$$Y = \frac{2\pi r_o}{Q_{flow} \rho C_p} \left[\frac{L_p}{\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} + L_B \left(\frac{1}{\frac{r_o}{h_i r_B} + \frac{r_o}{k_w} \ln \frac{r_i}{r_B} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} - \frac{1}{\frac{r_o}{h_i r_i} + \frac{r_o}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o}} \right) \right] \dots\dots\dots (E-7)$$

$$Y = \frac{2\pi}{Q_{flow} \rho C_p} \left[\frac{L_p}{\frac{1}{h_i r_i} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} + L_p L_{BD} \left(\frac{1}{\frac{1}{h_i r_i r_{BD}} + \frac{1}{k_w} \ln \frac{1}{r_{BD}} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} - \frac{1}{\frac{1}{h_i r_i} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} \right) \right] \dots\dots\dots (E-8)$$

$$Y = \frac{2\pi L_p}{Q_{flow} \rho C_p} \left[\frac{1}{\frac{1}{h_i r_i} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} + L_{BD} \left(\frac{1}{\frac{1}{h_i r_i r_{BD}} + \frac{1}{k_w} \ln \frac{1}{r_{BD}} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} - \frac{1}{\frac{1}{h_i r_i} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} \right) \right] \dots\dots\dots (E-9)$$

We now define the dimensionless temperature drop factor (F_{TB}) as the square bracketed term.

$$F_{TB} = \left[\frac{1}{\frac{1}{h_i r_i} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} + L_{BD} \left(\frac{1}{\frac{1}{h_i r_i r_{BD}} + \frac{1}{k_w} \ln \frac{1}{r_{BD}} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} - \frac{1}{\frac{1}{h_i r_i} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} \right) \right] \quad (\text{E-10})$$

$$F_{TB} = \left[\frac{L_{BD}}{\frac{1}{h_i r_i r_{BD}} + \frac{1}{k_w} \ln \frac{1}{r_{BD}} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} + \frac{1}{\frac{1}{h_i r_i} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} - \frac{L_{BD}}{\frac{1}{h_i r_i} + \frac{1}{k_p} \ln \frac{r_o}{r_i} + \frac{1}{h_o r_o}} \right] \quad (\text{E-11})$$

The term ‘ Y ’ can be simplified as Eq. 89,

$$Y = \frac{2\pi L_p}{Q_{\text{flow}} \rho C_p} F_{TB} \dots \dots \dots (\text{E-12})$$

and the dimensionless heat model for a partially-blocked pipe can be expressed as Eq. 90.

$$T_D = \left[\exp\left(-\frac{2\pi L_p}{Q_{\text{flow}} \rho C_p} F_{TB}\right) - 1 \right] + \frac{T_{mi}}{T_{amb}} \left[1 - \exp\left(-\frac{2\pi L_p}{Q_{\text{flow}} \rho C_p} F_{TB}\right) \right] \dots \dots \dots (\text{E-13})$$

VITA

Ebiaye Valerie Ombu was born in Edo, Nigeria on November 15, 1979, the daughter of Emmanuel Inatimi Ombu and Viola Kehinde Ombu. She attended Kwame Nkrumah University of Science and Technology, Kumasi, Ghana where she received a Bachelor of Science degree in chemical engineering in July 2001. In September 2002, she started work on a Master of Science degree in petroleum engineering at Texas A&M University, where she joined the Multiphase Research Group led by Dr. Stuart Scott. During that time, she was a 1st place sectional winner (Masters division) at the 2002 Texas A&M SPE Student Paper Contest for her paper titled, “Alternative Energy Sources for the Future, Fuel Cells?” She also completed an internship with Elf Petroleum Nigeria Limited as a member of the Well Performance Optimization team. She hopes to begin work with Halliburton in January 2005.
