Abstract and Introduction

Modifications to local and state codes are seen as an appropriate strategy for the prevention of residential air distribution system leakage and its impacts. A model code element has been developed to assist this strategy. Recent field studies of Florida residences by Cummings, Tooley and Moyer\(^1\) have revealed a mean leakage of 11 percent for the air distribution systems of central, fan-forced heating and air conditioning systems. Such leakage may cause an estimated 20 percent increase in energy consumption for air conditioning, as well as a 50 percent increase in peak heating load and an 80 percent increase in peak heating load. In addition, building air leakage may be expected to be several times greater when duct leakage is present or when avenues of air egress from closeable rooms are absent.

The model duct construction element presented here contains all of the standards, definitions and code language needed to replace the current duct construction element of the local or state code. The content of this paper was used as a principle source for language adopted for the 1991 Florida Energy Efficiency Code for Building Construction.

Addressed are the most appropriate standards required for the closure and sealing of metal duct, rigid fibrous glass duct, and nonmetallic flexible duct. Also addressed are (1) detailed requirements for the sealing of mechanical closets when they function as plenum chambers, (2) detailed requirements for the sealing of enclosed support platforms for air handlers and furnaces when they function as return duct, (3) detailed requirements for the sealing of uninhabitable cavities of the building structure, when they function as duct, and (4) detailed requirements for the egress of air from enclosed rooms which receive supply air. Where necessary, commentary is provided to explain the options available for implementing the model code provision as well as its ramifications.

All provisions of this model code are compatible with the requirements, standards and guidelines contained in related documents published by the following organizations: the Southern Building Code Congress International, Inc., the Sheet Metal and Air Conditioning Contractors National Association, the American Society of Heating, Refrigerating and Air Conditioning Engineers, Underwriters Laboratories, Inc., the Air Conditioning Contractors of America, the Thermal Insulation Manufacturers Association, the National Fire Protection Association, and the Gypsum Association.

Table Of Contents

100.0 HVAC Air Distribution Systems

(a) Air Distribution System Component Construction

1. Metal duct systems, rigid and flexible.
2. Nonmetallic duct systems, flexible.
3. Fibrous glass duct systems, rigid.
4. Installation and application procedures for the use of pressure-sensitive, aluminum foil-backed tapes.
5. Combination duct systems.
6. Terminal and intermediate fittings.
7. Air handling units.
8. CAVITIES of the building structure.
(b) Mechanical Closets and Enclosed Support Platforms
1. Mechanical closets meeting the definition of plenum chamber.
2. Enclosed support platforms containing return duct.
3. Treatments of through-wall, through-floor, and through-ceiling returns.
(c) Air Duct System Insulation
(d) Return Air Requirements

Appendix: Definitions
Appendix: Standards

100.0 HVAC Air Distribution Systems

In the matter of duct sealing and insulation, the provisions of this code shall supersede all other codes and standards. The purposes of the provisions of this section are to preclude the unintentional leakage of air into or out of the air distribution system and to control thermal gains and losses resulting from conduction.

(a) Air Distribution System Component Construction

When the components of the air distribution systems, as defined by the subsections of this section, are constructed and sealed according to the requirements of this section, including the standards as referenced by and as limited by this section, they shall be deemed to be substantially airtight and shall be deemed as meeting the intent of this code.

Proceedings of the Seventh Symposium on Improving Building Systems in Hot and Humid Climates, Fort Worth, TX, October 9-10, 1990
1. Metal duct systems, rigid and flexible.
   a. All ducts and duct fittings (see Definitions) located outside of the conditioned bound-
      ary of a building shall be sealed to meet the requirements of Standard SMAC-1, which pro-
      vides that all transverse joints, longitudinal seams and duct wall penetrations shall be
      sealed. However, round or oval metal ducts, operating below one (1) inch water
gauge and utilizing a snap-lock longitudinal seam shall be exempt from the required seal of the longitudinal seam. If
   b. Duct systems designed to operate at pressures greater than (3) inches water gauge (equiva-
      lent pressure equal to the design duct pressure class) shall be sealed to Seal Class A
      requirements of Standard SMAC-1, and tested in accordance with the equivalent perfor-
      mance which is certified by a marking of "UL 181A-P on the duct fitting using one of the following four
      materials: (1) gasketing, (2) a mastic, (3) a mastic-plus-embedded fabric, or (4) a pres-
      sure-sensitive tape certified to meet Part I of UL-2 (UL181A), when such part shall be-
      come effective. In no case shall tapes utilizing rubber-based adhesives be used.
      a) Sealing systems shall be installed ac-
      cording to the installation and application procedures of TIMA-4. Only sealing materials enumerated below shall
      meet Class 1 Surface Burning standards (see Definitions). All sealing materials enumerated below shall
      meet ASTM E 84, and of TIMA-1.
      b) Pressure-sensitive tapes. Where in-
      dicated in Section 100.0(a)4., pressure-
      sensitive tapes may be used, provided that they utilize an acrylic-based adhesive and that the installa-
      tion and application procedures of Section 100.0(a)4., and of TIMA-1 are observed. Pressure-sensitive
      tapes utilizing rubber-based adhesives shall not be used.
      c) Mechanical fastening to mechanical equip-
      ment. When a section of metal duct is
      joined to mechanical equipment, there shall be established sufficient mechanical fastening between the duct and mechanical equipment to support the duct indepen-
      dently of the duct system. For this application under another part of UL-2 (UL181A), as indi-
      cated by a marking of "UL 181A-P" on the tape, a pressure-sensitive tape having equivalent performance which is certified for this application is another part of UL-2 (UL181A), when such part shall be-
      come effective. In no case shall tapes utilizing rubber-based adhesives be used. When an approved tape is used, the fol-
      lowing procedures shall be observed: (a)

3 A joint study group of ASHRAE, SMACNA and TIMA, reported by ASHRAE 1986 Fundamentals Handbook, Chapter 32, found very low leakage for the unsealed longitudinal lapweld of round snap-
   lock metal ducts, such ducts operating at pressures of one (1) inch water gauge and below.
4 This specification is consistent with ASHRAE Standard 90A, a
   2. Nonmetallic flexible duct systems.
   Nonmetallic flexible duct, comprised of a wire-reinforced inner lining, an insulation layer and an outer jacket, shall be sealed and fastened to all mechanical equipment components using a duct fitting (see Definition). All
   sealing materials enumerated below shall
   meet ASTM E 84, and of TIMA-1.

   b) Longitudinal seams. Closure options shall be limited either to mastic-plus-embedded-fabric, or to pressure-sensitive tape utilizing an acrylic-based adhesive.
   b) Longitudinal seams. Closure options shall be limited to mastic-plus-embedded fabric and to pressure-sensitive tape utilizing an acrylic-based adhesive. However, round or oval metal ducts utilizing a snap-lock longitudinal seam shall be exempt from the required seal of the longitudinal seam.
   c) Conditions on the use of closure sys-
   tems. (a) Mastic-plus-embedded-fabric. Such closure systems shall be installed ac-
   cording to the installation and applica-
   tion procedures of TIMA-1. Follow-
   ing the adoption of standard UL 181A, mastic-plus-embedded-fabric systems, such closure systems shall meet this standard.

3. The tested duct leakage class, at a test
   pressure equal to the design duct pressure
   class, shall be equal to or less than
   Leakage Class 3. Leakage testing may be
   limited to representative sections of the
duct system but in no case shall such tested sections include less than 25 percent of the total installed duct area and 25 percent of the transverse joints for the designated pressure class.

3. The tested duct leakage class, at a test
   pressure equal to the design duct pressure
   class, shall be equal to or less than
   Leakage Class 3. Leakage testing may be
   limited to representative sections of the
duct system but in no case shall such tested sections include less than 25 percent of the total installed duct area and 25 percent of the transverse joints for the designated pressure class.

   c. Duct systems designed to operate at three (3) inches water gauge pressure class shall be sealed to Seal Class A requirements of Standard SMAC-1.
   d. Duct systems designed to operate at two (2) inches water gauge pressure class or lesser shall be sealed as a minimum to Seal Class B requirements, with the transverse joints and longitudinal seams shall be sealed.

   d. Duct systems designed to operate at (two) inches water gauge pressure class or lesser shall be sealed as a minimum to Seal Class B requirements, with the transverse joints and longitudinal seams shall be sealed.

   e. Duct systems designed to operate at one (1) inch water gauge pressure class shall be sealed to Seal Class A requirements of Standard SMAC-1, and tested in accordance with Standard SMAC-3. The tested duct leakage class, at a test
   pressure equal to the design duct pressure
   class, shall be equal to or less than
   Leakage Class 3. Leakage testing may be
   limited to representative sections of the
duct system but in no case shall such tested sections include less than 25 percent of the total installed duct area and 25 percent of the transverse joints for the designated pressure class.

   f. Duct systems designed to operate at one (1) inch water gauge pressure class shall be sealed to Seal Class A requirements of Standard SMAC-1, and tested in accordance with Standard SMAC-3. The tested duct leakage class, at a test
   pressure equal to the design duct pressure
   class, shall be equal to or less than
   Leakage Class 3. Leakage testing may be
   limited to representative sections of the
duct system but in no case shall such tested sections include less than 25 percent of the total installed duct area and 25 percent of the transverse joints for the designated pressure class.

   g) Duct systems designed to operate at one (1) inch water gauge pressure class shall be sealed to Seal Class A requirements of Standard SMAC-1, and tested in accordance with Standard SMAC-3. The tested duct leakage class, at a test
   pressure equal to the design duct pressure
   class, shall be equal to or less than
   Leakage Class 3. Leakage testing may be
   limited to representative sections of the
duct system but in no case shall such tested sections include less than 25 percent of the total installed duct area and 25 percent of the transverse joints for the designated pressure class.

   h. Duct systems designed to operate at one (1) inch water gauge pressure class shall be sealed to Seal Class A requirements of Standard SMAC-1, and tested in accordance with Standard SMAC-3. The tested duct leakage class, at a test
   pressure equal to the design duct pressure
   class, shall be equal to or less than
   Leakage Class 3. Leakage testing may be
   limited to representative sections of the
duct system but in no case shall such tested sections include less than 25 percent of the total installed duct area and 25 percent of the transverse joints for the designated pressure class.

   i. Duct systems designed to operate at one (1) inch water gauge pressure class shall be sealed to Seal Class A requirements of Standard SMAC-1, and tested in accordance with Standard SMAC-3. The tested duct leakage class, at a test
   pressure equal to the design duct pressure
   class, shall be equal to or less than
   Leakage Class 3. Leakage testing may be
   limited to representative sections of the
duct system but in no case shall such tested sections include less than 25 percent of the total installed duct area and 25 percent of the transverse joints for the designated pressure class.

   j. Duct systems designed to operate at one (1) inch water gauge pressure class shall be sealed to Seal Class A requirements of Standard SMAC-1, and tested in accordance with Standard SMAC-3. The tested duct leakage class, at a test
   pressure equal to the design duct pressure
   class, shall be equal to or less than
   Leakage Class 3. Leakage testing may be
   limited to representative sections of the
duct system but in no case shall such tested sections include less than 25 percent of the total installed duct area and 25 percent of the transverse joints for the designated pressure class.
all unnecessary substances which may diminish the bond, including dust, dirt, oil, grease and moisture, shall be removed entirely from all receiving surfaces; (b) the tape, which shall be free of punctures, shall be applied such that it extends a minimum of 2 inches onto the duct lining and 1.5 inches onto the duct fitting, with all tape overlaps exceeding 1 inch; (c) the tape shall be fastened to the duct lining and fitting, and the insulation layer. The outer jacket shall not be attached to the duct product (fibrous glass duct board or sheet metal) at the other end of the duct. (d) The tape shall be made to form a right angle in either its long or short dimension, and (d) the tape shall be burried to the flange and will extend a minimum of one inch onto the duct board.

In no instance shall any part of a non-metallic flexible duct section be interposed between the flange of the duct fitting and the rigid duct board or sheet metal. Nonmetallic flexible ducts shall be configured and supported so as to prevent the use of excessive duct lengths, to prevent duct and joint dislocation or damage, and to prevent constriction of the duct below the rated duct diameters. The following requirements shall apply to all nonmetallic flexible air ducts and air connectors:

1. Ducts shall be supported at the manufacturer's recommended intervals, but in no case shall the distance between supports exceed 10 feet. Ducting between supports shall not exceed 1/2 inch per foot of spacing between supports.

2. The length of duct material used for a given run, if extended, shall not exceed more than five (5) percent the minimum extended length needed for that run. Ducts shall be installed fully extended.

3. Ducts shall be supported within 1.5 feet of an intermediate fitting when the intermediate fitting is attached to the flange-end to fibrous glass duct board. All supports shall be distinct from the duct system and shall maintain contact with the lower one-half of the circumference of the outer jacket. When a bend is to occur near an intermediate fitting, the duct shall be extended straight outward from the fitting for several inches before beginning the bend, and the duct shall be supported between the fitting and the bend. Terminal fittings shall be supported independently of the flexible duct.

4. The inside diameter of a bend shall exceed the outside diameter of the specific duct product undergoing the bend. Long horizontal duct runs with sharp bends shall have supports before and after the bend, located within one (1) duct diameter of the duct board.
3. Fibrous glass duct systems.

All rigid fibrous glass ducts and plenums shall be constructed according to the provisions of Standard TIMA-1 as modified by the conditions below.

a. Where they must be sealed. All transverse joints, longitudinal seams and duct wall penetrations shall be sealed. All joints and seams are affected, including, but not limited to, the joints between sections of duct and the joints between duct and other distribution system components, such as terminal and intermediate fittings and the supply and return-ends of air handler and furnace cabinets. When a section of duct, fabricated of fibrous glass duct board, is joined to mechanical equipment, there shall be established sufficient mechanical fastening between the duct and mechanical equipment to support the duct independently of the closure system.

b. Closure system requirements. All closure products shall be used in accordance with standard TIMA-1 and the air barrier (see Definitions) of the material in order to form a continuous barrier to the leakage of conditioned air. One of the following groups of closure products shall be used:

1) Closure products which are in accord with the manufacturer’s Listing for the use of a tab-ring. The ring strengthens the attachment against torque of TIMA-1, Section III, including but not limited to the following requirements:

a. Surface preparation. The surfaces upon which closure products are to be applied shall be clean and dry. Dust, oil, grease, moisture and other unnecessary substances which may diminish the bond shall be removed entirely, by solvents if necessary, from the receiving surface.

b. Cold weather conditions. At temperature below 50°F, pressure-sensitive tapes shall not be used, unless the following conditions have been achieved: (1) that the tape will have been maintained at a temperature of 70°F during use and for 12 hours prior to use, or (2) that immediately prior to applying the tape the receiving surface has been pre-heated by the application of a 400° ± 25°F iron. The tape application. The tape shall be centered over the joint or seam, and shall be burnished to the extent that the underlying patterns of the seam (and for fibrous glass duct board the seams patterns of the seam) are uniformly adhered, and it shall be free of wrinkles. It shall be uniformly adhered, and it shall be free of punctures.

5. Combination duct systems.

Duct systems combining metal, fibrous glass or nonmetallic flexible ducts shall meet the sealing requirements of Class 1 Surface Burn- ing standards, at minimum, and shall be used in accordance with standard TIMA-1 and the air barrier (see Definitions) of the material in order to form a continuous barrier to the leakage of conditioned air. One of the following groups of closure products shall be used:

1) Closure products which are in accord with the manufacturer’s Listing for the use of a tab-ring. The ring strengthens the attachment against torque of TIMA-1, Section III, including but not limited to the following requirements:

a. Surface preparation. The surfaces upon which closure products are to be applied shall be clean and dry. Dust, oil, grease, moisture and other unnecessary substances which may diminish the bond shall be removed entirely, by solvents if necessary, from the receiving surface.

b. Cold weather conditions. At temperature below 50°F, pressure-sensitive tapes shall not be used, unless the following conditions have been achieved: (1) that the tape will have been maintained at a temperature of 70°F during use and for 12 hours prior to use, or (2) that immediately prior to applying the tape the receiving surface has been pre-heated by the application of a 400° ± 25°F iron. The tape application. The tape shall be centered over the joint or seam, and shall be burnished to the extent that the underlying patterns of the seam (and for fibrous glass duct board the seams patterns of the seam) are uniformly adhered, and it shall be free of wrinkles. It shall be uniformly adhered, and it shall be free of punctures.

6. Terminal and intermediate fittings.

Fitting subsections. All seams and joints within duct fittings (see Definitions) and between fitting subsections through which air leakage could occur, if unsealed, shall be sealed. If the seam or joint occurs between sections of fibrous glass duct board, the closure systems approved for fibrous glass ducts, Section 100.0(a), shall be used. If the seam or joint occurs between sections of fibrous glass duct board, the closure systems approved for fibrous glass ducts, Section 100.0(a), shall be used.

Fitting to duct joints. Joints between metal duct and duct fittings, including mechanical equipment, shall be sealed according to the provisions of Section 100.0(a)1., and seams between fibrous glass duct and duct fittings, including mechanical equipment, shall be sealed according to the provisions of Section 100.0(a)2b. When a tab-fastened fitting is joined to duct board, all functional tabs shall be employed in securing the fitting. (Optional) and the fitting shall incorporate a ring of one (1) inch minimum width between the tabs of the fitting and the duct board.
The ring shall be sufficiently rigid to distribute uniformly the forces applied by the

7. Air handling units. All air handling units located outside the conditioned space shall be sealed to the equivalent of Seal Class-A of Standard SMACN-1, which provides that all joints, seams and penetrations be sealed.

8. Cavities of the building structure. a. When uninhabitable cavities of the building structure are used to transport air between a heating or air-conditioning unit (HAC unit) and air distribution system return inlet(s) or supply outlet(s), these cavities shall be so sealed as to preclude the possibility of any air leakage between them and any non-conditioned space or between them and any building cavity not intended for this air transport. Such uninhabitable cavities shall be sealed but shall not be limited to soffits, wall cavities and through-wall transfer grilles, whether or not such cavities are attached directly to return or supply duct or to the HAC unit.

b. Seals and sealants used to close such cavities shall be limited to either mastics or mastics-plus-embedded-fibers and shall meet standard SMAC-1, Section 1.5, which requires prudent selection and application of sealing materials. Y-material specifications for the necessary air containment materials and sealants, are absent from the local mechanical code, the air containment materials and sealants utilized shall meet Class 1 Surface Burning standards.

c. All ducts, including all duct located in duct chases, when they penetrate the building envelope, shall be sealed directly to that component of the building envelope (ceiling, floor or wall) which is penetrated using, where necessary, acceptable materials to bridge the spaces between the duct and the building envelope components.

(b) Mechanical Closets And Enclosed Support Platforms For Central Air Conditioning And Heating Systems

Mechanical closets. A mechanical closet for a central heating or air conditioning unit (HAC unit) is considered a plenum chamber, if return air, when it enters the mechanical closet, is continuous with the supply duct of the HAC unit and provides a housing for the transport of return air from the return air inlet(s) to the inlet of the heating or air conditioning unit, the platform shall contain a duct section fabricated to contain without leakage the return-air stream. Such support platforms and return duct sections, whether they are located inside or outside the conditioned space, shall meet the requirements of section 100.0(b), below.

Enclosed support platforms. When an enclosed platform supports a central heating unit or the air handler of a central air conditioner or heat pump and provides a housing for the transport of return air from the return air inlet(s) to the inlet of the heating or air conditioning unit, the platform shall contain a duct section fabricated to contain without leakage the return-air stream. Such support platforms and return duct sections, whether they are located inside or outside the conditioned space, shall meet the requirements of section 100.0(b), below.

1. Mechanical closets meeting the definition of plenum chamber. When a mechanical closet meets the definition in 100.0(b) of a plenum chamber, regardless of its location, it shall be sealed in such a way as to preclude any air leakage into the return air stream from the cavities of adjoining walls or from outside the conditioned space. Sealing shall be accomplished by implementing Part a., below, using materials as required by Part b.

a. Part a. Establishing a continuous air barrier (see Definitions) on the inside surface of a mechanical closet functioning as a plenum chamber. 1) Air barrier location. The interior walls, ceiling chamber of a mechanical closet shall be sealed continuously, with a panelized material, which may be gypsum wallboard, capable of performing the function of an air barrier, and it shall meet the material requirements described below in 100.0(b)1a. The floor of the mechanical closet may be excluded from this requirement if its construction within the sealed portion of the mechanical closet is continuous, fissure-less concrete.

b. Seals and sealants. (1) A sealant meeting the material requirements below shall be used to seal all joints between wall sheathing panels and the platform, between the bottom plate and the floor, between wall and ceiling and between the first and second floor and the mechanical closet on the floor. The first floor is often in hydraulic communication. If, in a direct free-air return is used, the attic air may be drawn into the return air stream.

9 This code language eliminates the need to establish the original leakage air as air from outside the conditioned space. It is often perceived, incorrectly, that air leakage is not the origin of return air. However, with the mechanics of the hydraulic commmication, it is often argued, in error, that air leakage from wall cavities into a mechanical closet located on the first floor of a two-story building could not have its origin outside the conditioned space. In test this could well be the case, with air entering second floor partition walls from the attic, passing through the between-floor space and into first floor partition walls.

8 When an air handler is on the first story of a two-story dwelling, a chase is often used to route duct to the attic for air delivery to the second floor. As a result of this chase, the attic and the space between the first and second floor and the mechanical closet on the first floor are often in hydraulic communication. And, if a direct free-air return is used, the attic air may be drawn into the return air stream.

Proceedings of the Seventh Symposium on Improving Building Systems in Hot and Humid Climates, Fort Worth, TX, October 9-10, 1990
panels, between wall panels and the door jamb, and between wall panels and the air handler support platform, if one is present. Panel adhesion wall paneling shall be sealed to each other using a sealant meeting the material requirements of this section. Gypsum wallboard joint compound shall not be an acceptable sealant. If the sealant is gypsom wallboard, sealants may be omitted at flat, vertical butt joints, only, provided that the gyspum wallboard panels are attached via adhesives meeting standard ASTM C 557, and are installed in accordance with Section 2 of Standard GYPS-I, which recommends that a separate bead of adhesive be placed between each panel and the common vertical framing member.

3. Penetrations. All air ducts, service lines, refrigerant lines, electrical wiring, condensate drain lines, mechanical equipment support platforms, and all other objects, excluding sheathing fasteners, which penetrate the sheathing of the ceiling, walls, or floor of the mechanical closet, shall be sealed to this sheathing, or floor if it is penetrated, on the inside surface using a sealant meeting the material requirements below in 100.0(b)3. The refrigerant line chase, if it emerges within the mechanical closet, shall be sealed to close both inside and inside openings.

b. Part b. Material requirements.

1. Sheathing material. The sheathing material is to meet the following standards: (a) it shall have an air porosity (see Definitions) no greater than that of a duct penetration meeting standard UL-11 [UL181], Section 22, that of undamaged, intact one-half inch thick gypsom wallboard gypsum board; (b) it shall meet Class 1 Surface Burning standards. In addition, the provisions of local me-

10 Sealants to meet this Class 1 Surface Burning requirement are not difficult to acquire. Many sealants, such as the Ohio Sealant Water Base Sound Sealant, are available at gyspum dealers and cost approximately $4.00 per one quart tube. Some brands which meet the Class 1 Surface Burning standard are: Ohio Sealant Rubber Base Sound Sealant (800 342-05m), Tremco Gypsum Acoustical (Water Base) Sealant (800 321-3578), Tremco Epoxy Acoustical (Rubber Base) Sealant (800 321-3578), Tremco Acoustical (Rubber Base) Sealant (800 321-7966), and US Gypsum Acoustical (Water Base) Sealant (800 324-0088).

11 If there is a support platform which is attached by ledgers to the wall framing (which can happen, because air handlers are often hung from the ceiling, walls or floor of the mechanical closet to achieve a seal, for the following reasons: (a) it does not adhere to worst. If it would not form a seal between the gyspum wallboard and the door jamb and between the return air intake(s) from the gyspum wallboard and the door jamb and between the return air intake(s) from the air handler support platform, if one is present; (b) adjoining wall panels and all UL181 rated fibrous glass duct boards meet Class 1 Surface Burning standards. In addition, the provisions of local mechanical codes related to plenum chambers shall further define acceptable sheathing materials. If gyspum glass duct board is used, its foil air barrier shall face the inside of the mechanical closet.)

2. Enclosed support platforms containing return ducts. a. Mandatory duct section. When an enclosed support platform is located between the return air intake(s) from conditioned space and the inlet of the air handling unit or furnace, it shall contain a duct section constructed entirely of rigid fibrous glass duct board or rigid sheet metal and be insulated according to the requirements of Section 100.0(c). The duct section shall be so designed and so constructed that (1) no portion of the support platform or of the building structure, including adjoining walls, floors and ceilings, shall be in contact with the return air stream or function as a component of that duct section; and (2) the duct section shall be effectively isolated from the building structure, so that air

13 For example, the Standard Mechanical Code, Section 60(b), provides that this sealing material and the floor covering must be either non-combustible materials or must meet Class 1 Surface Burning standards (see Definitions). Most gyspum wallboards and all UL181 -rated fibrous glass duct boards meet the Class 1 Surface Burning standards.

14 Section 1 of 9-181-1 allows rigid fibrous glass or steel ducts and prudent selection and application of sealing methods.

15 For example, the Standard Mechanical Code, Section 509, requires that all partitions meet Class 1 Surface Burning standards.

16 Joint compound should not be used at any location in the plenum chamber to achieve a seal, for the following reasons: (a) it does not adhere to worst. If it would not form a seal between the gyspum wallboard and the door jamb and between the return air intake(s) from the gyspum wallboard and the door jamb and between the return air intake(s) from the air handler support platform, if one is present; (b) adjoining wall panels and all UL181 rated fibrous glass duct boards meet Class 1 Surface Burning standards. In addition, the provisions of local mechanical codes related to plenum chambers shall further define acceptable sheathing materials. If gyspum glass duct board is used, its foil air barrier shall face the inside of the mechanical closet.)

Proceedings of the Seventh Symposium on Improving Building Systems in Hot and Humid Climates, Fort Worth, TX, October 9-10, 1990
cannot be transferred to the return air stream from the cavities of adjoining walls, floors or ceilings.

b. Closure requirements. The subsections of this duct section and its joining to the mechanical equipment and to all other connecting duct sections shall be attached and sealed according to the respective requirements of section 100.4(a), to the extent that this closure effort shall preclude over the entire surface area of the duct section, including those areas not exposed to view, any present or future possibility of air leakage into the return air system.

c. Penetrations of the duct section. (Choose one of the following two options, A or B.)

[Option A:] In no instance shall a refrigerant line, refrigerant line, wiring, pipe or any other object or product (including penetrant) within the support platform. As a result, if it emerges within this duct section, shall be sealed to both its inside and outside surfaces.)

[Option B:] All objects penetrating this duct section shall be sealed to its air barrier (see Definition) and the refrigerant line chase, if it emerges within this duct section, shall be sealed to close both its inside and outside openings.

d. Non-supporting enclosures. Enclosures, which are located directly below mechanical closets and which house passageways for return air, but which may not physically support mechanical equipment, are also covered by the requirements of this subsection.

3. Treatments of through-wall, through-floor, and through-ceiling returns used to convey air from a return air inlet to a Mechanical Client functioning as a plenum chamber or to an Enclosure Support Platform containing return duct. When a through-wall, through-floor or through-ceiling return is used, wire framing or fiberglass glass duct board shall be installed within the wall, floor or ceiling cavity so as to surround the opening continuously, thereby isolating the return air passageway from the remainder of the cavity. The segments of this framing or duct board shall be sealed to each other, and this framing or duct board air barrier shall be sealed to the air barriers of the sheathing or duct board inside the mechanical closet or enclosed support platform and (b) the gypsum wallboard or other wall, ceiling or floor paneling on the air-inlet or outlet side of the opening. The effect of such treatment shall be to prevent the possibility of air leakage into the return air stream from the remainder of the wall, ceiling or floor cavity.

4. Insulation requirements and effective dates. Prior to effective date, all air distribution system components, including, but not limited to, ducts, duct fittings, supply plenums, enclosures in or on buildings, or portions thereof, shall be insulated to provide a minimum thermal resistance, excluding air film resistances, of R-4.2.

As of the effective date, the minimum installed thermal resistance for all air handling system components shall be R-6.0. The Code requires that all flexible ducts of 4 inches or less that are located inside of a conditioned space, shall be insulated to meet these requirements. With the implementation of a building code that requires the floor of a plenum chamber, and if plenum chamber floor is located above a non-conditioned space, the floor shall be insulated to meet these requirements.

5. Air Distribution System Insulation

All duct insulation values shall be determined by using flat specimens to determine thermal resistance (R) using the relationship

\[
R = \frac{t}{k},
\]

where t is the insulation thickness and k is the thermal conductivity.

For such products the nominal value shall be used for thickness.

Insulation for nonmetallic flexible ducts. Such insulation shall be tested at a thickness equal to the installed duct wall thickness. The installed duct wall thickness shall be determined by circumferentially cutting the outer jacket and insulating from a sample, removing it from the inner lining, laying it into a flat surface and measuring its width with a rule, to the nearest 1/16 inch. The installed R-value of the air duct or air connector, calculated in accordance with this standard, shall be projected or labeled on the product at 10 feet intervals, maximum. All duct systems, plenums, and enclosures installed in or on buildings shall be thermally insulated as follows:

1. Insulation requirements and effective dates. Prior to effective date, all air distribution system components, including, but not limited to, ducts, duct fittings, supply plenums, enclosures in or on buildings, or portions thereof, shall be insulated to provide a minimum thermal resistance, excluding air film resistances, of R-4.2.

As of the effective date, the minimum installed thermal resistance for all air handling system components shall be R-6.0. The Code requires that all flexible ducts of 4 inches or less that are located inside of a conditioned space, shall be insulated to meet these requirements. With the implementation of a building code that requires the floor of a plenum chamber, and if plenum chamber floor is located above a non-conditioned space, the floor shall be insulated to meet these requirements.

6. Insulation requirements and effective dates. Prior to effective date, all air distribution system components, including, but not limited to, ducts, duct fittings, supply plenums, enclosures in or on buildings, or portions thereof, shall be insulated to provide a minimum thermal resistance, excluding air film resistances, of R-4.2.

As of the effective date, the minimum installed thermal resistance for all air handling system components shall be R-6.0. The Code requires that all flexible ducts of 4 inches or less that are located inside of a conditioned space, shall be insulated to meet these requirements. With the implementation of a building code that requires the floor of a plenum chamber, and if plenum chamber floor is located above a non-conditioned space, the floor shall be insulated to meet these requirements.
2. Additional insulation requirements.

Additional insulation with vapor barrier shall be provided where the minimum duct insulation requirements of subsection 1, above, are determined to be insufficient to prevent condensation. However, insulation may be omitted when it can be shown that the criteria in subsection 1, above, have been met and that condensation resulting from its absence will not be detrimental to the distribution system, mechanical system or building structure, and that the health and safety of the building occupants will not be adversely affected.

3. Omission of duct insulation.

Duct insulation (except where required to prevent condensation) is not required in any of the following cases:

a. Where the heat gain or loss of the ducts, without insulation, will not increase the energy requirements of the building.

b. Exhaust air ducts.

c. Crawlspace plenums.

4. Required Net Free Grille Area

Crawlspace plenums, whether sealed or unsealed, shall not be used as supply or return plenums.

(d) Return Air Requirements

All rooms, enclosed by a door and to which conditioned air is supplied, shall be equipped with a means for air egress, so that conditioned air will be able to return to the air handler or furnace. The size of the return air grille or outlet area shall be determined according to the following:

1. Ducted returns.

If conditioned air is to be removed from an enclosed room by means of a ducted return, the design and size of the return duct and return grille should be determined using the methods of ASHR-1 or ACCA-1, or another approved method. However, in the absence of such sizing being performed, the size of the return grille shall be determined in the following manner:

a. Non-filtered return grille of a ducted return: Required Net Free Grille Area (in Square Inches) = Supply Air CFM multiplied by 0.36 SqIn/CFM (For each 100 CFM of Flow Air there shall be 36 Square Inches of Net Free Grille Area, 2 12 percent);

b. Filtered return grille of a ducted return: Required Net Free Grille Area (in Square Inches) = Supply Air CFM multiplied by 0.50 SqIn/CFM (For each 100 CFM of Flow Air there shall be 50 Square Inches of Net Free Grille Area, 23).

Note that this is not a sizing calculation for return duct. The Return Duct size should be determined using the duct design procedures of ASHR-1 or ACCA-1, or another approved method.

2. Other, non-ducted methods of air egress.

If conditioned air is to exit an enclosed room by means of a through-wall grille, a through-door grille, an under-cut door, or by another non-ducted means, the Net Free Grille Area or Outlet Area shall equal or exceed the area determined by the following:

Required Net Free Grille Area (in Square Inches) = Supply Air CFM multiplied by 0.36 SqIn/CFM (For each 100 CFM of Supply Air there shall be 36 or more Square Inches of Net Free Grille or Outlet Area).

If an under-cut door is to be used for air egress, the arithmetic product of the door width times the distance between the door and the finished floor at its most restrictive location shall equal or exceed the Required Net Free Outlet Area. If the floor is finished with carpet, the distance shall be measured from the bottom of the door to the trip of the uncompressed carpet sap.

If a through-wall, through-door or through-ceiling grille is to be used, the wall penetr-ation shall receive the treatments of section 100.0(a)(8) and 100.00(a)(10).

Appendix: Definitions

Air Barrier or Air Containment Material. When used in relation to air duct and plenum chambers, it is a material (1) which is used in direct contact with supply or return air as part of the air distribution system and (2) which has an air porosity no greater than that of a duct product meeting standard UL-1, Section 22, or of undamaged, intact one-half inch thick gusps wallboard as defined by ASTM C 36. The air barrier or air containment material may be a uniform panel, such as gypsum wallboard meeting ASTM C 36, which as a whole meets this air porosity standard, or it may be a foil or other membrane, such as the foil cladding on fibrous glass duct board, which alone meets this air porosity standard, but which is attached as a composite to a panelized material.

Air Duct. A conduit or passageway for transporting air to or from heating, cooling, air conditioning, or ventilating equipment. Included in this definition are supply plenums as well as air ducts and air connectors as referred to by UL161 and NFPA 90A and NFPA 90B.

Notes

22 The Net Free Grille Areas are derived from ACCA Manual D (1984) p. 25, which recommends a 400 FPM face velocity at return grilles and from SMACNA SMAC-4, p. 8.2, which states Return air grilles shall be sized to return 100 percent of the air being supplied to the conditioned space with air velocities not to exceed 450 FPM face velocity.

23 Note also that in order to comply with standard SMAC-4, ducted returns shall not be used for air egress from bathrooms, kitchens, utility spaces, spaces used for storage of fuel or flammable materials, or from a confined space in which a draft diverter or shut regulator is located or to which combustion air is supplied. In these cases, non-ducted means of air egress should be used.
Air Porosity. A measure of the ability of a material to transmit air through the plane of the material.

Class. A classification, based on the pressure differential between the faces of a sheet of material. This product meets Class 1 Surface Burning standards if it exhibits the following surface burning characteristics when tested under either UL 723 or ASTM E 84 test procedures: a Flame Spread Rating of not over 25 without evidence of continued progressive combustion and a Smoke Developed Rating of not over 50. Compliance with this product definition is not equivalent to compliance with UL Standard 181. However, since the UL 723 test procedure is one part of the UL 181 standard, all products meeting the UL 181 standard also satisfy this definition. It is not mandatory that a product be tested solely by UL but only that it be tested under either UL 723 or ASTM E 84 test procedures.

Duct Fitting. A general expression for all couplings used to join sections of nonmetallic flexible duct. The clamp, when tightened, shall fasten either the inner lining or the outer jacket to the duct fitting. A raised head should be present on the duct fitting to prevent movement of the draw tie and to prevent separation of the union. Tension ties, clinch bands, draw bands, and straps are considered draw ties.

Duct Fitting. A general expression for all couplings used to join sections of air duct to other distribution system components. Duct fittings are used to join separate sections of nonmetallic flexible duct or to join a section of nonmetallic flexible duct to another distribution system component. Duct fittings may be classified as either terminal fittings or intermediate fittings. Terminal fittings join a section of flexible duct to other types of duct air duct to supply outlets and return inlets at the ends of the distribution system; they class of fittings includes register and return boots and register boxes. Intermediate fittings join a section of nonmetallic flexible duct to sections of other types of duct such as rigid fibrous glass duct board, and to mechanical equipment components such as air handlers and furnaces; this class of fittings includes collars, take-offs, tapping sleeves, and adapters. A raised head or an indented groove should be present on the duct fitting to prevent movement of the draw tie and thus detachment of the outer jacket from the duct fitting.

Enclosed Support Platform. A framed enclosure which supports a central heating unit or the air handler of a central air conditioning unit. When such an enclosed platform provides a housing for the transport of return air from the return air inlet(s) to the inlet of the heating or air conditioning unit, the platform must contain a return section of ductwork which contains without leakage the return air stream. In jurisdictions which have adopted the Standard Mechanical Code, materials used in constructing return ducts, if located within two feet of the heating unit casing, must meet either Class 0 or Class 1 Surface Burning standards. At distances of two feet and greater, return duct materials may be less fire resistant than Flame Spread Ratings of 250. Refer to Section 510, Standard Mechanical Code, for additional information on allowable materials. To meet the requirements of the National Fire Protection Association Standard 501, which is incorporated by reference into the Standard Mechanical Code, the section of nonmetallic flexible duct which contacts the air stream, is a wire-reinforced jacket often made of plastic.

Infiltration. The uncontrolled air leakage through cracks and openings in any building element and around windows and doors of a building, caused by the pressure effects of wind. HVAC distribution system leaks or the effect of differences between the indoor and outdoor air densities.

Integral-Flange Duct Fitting. A type of intermediate duct fitting. To be an integral-flange duct fitting, the fitting must have a flange of 5/8 inch minimum width which is mechanically attached to and sealed to the cylinder or sleeve of the fitting. A function of this flange is to provide a surface which can be sealed to rigid duct board.

Mechanical Closet. A room which contains the blowout of a central heating or air conditioning unit, which is less than 60 square feet in floor area, and which is enclosed by either a solid or louvered door. A mechanical closet may or may not be a plenum chamber.

Nonmetallic Flexible Duct. A type of round flexible air duct comprised of a three-layer composite. The innermost layer, which contacts the air stream, is a wire-reinforced inner lining or a layer often made of plastic and reinforced with a helical wire an insulation blanket. And, the outermost layer is a scrim-reinforced jacket often made of plastic.

Plenum Chamber. A mechanical closet for a central air conditioning or heating unit is considered a plenum chamber, if return air, when it enters the mechanical closet, is confined by the walls, ceiling and floor of the mechanical closet during its journey to the air handler, so that the outer walls of the air handler or furnace are exposed to the air stream when it exits the mechanical closet to the supply and return plenums. Plumbing and electrical wiring components are plenum chambers, their walls, ceilings, floors and other contents are regulated by the Standard Mechanical Code either (a) to materials which are non-combustible tested under standard ASTM E 130 or (b) to combustible materials which meet Class 1 Surface Burning standards; Flammable Spread 25, Smoke Developed 50. For residential buildings, wood frame mechanical equipment supports and approved plumbing and electrical wiring are exempted by this mechanical code from these non-combustible requirements. The Standard Mechanical Code in Chapter 2, Definitions, apparently includes gypsum wallboard in its definition of non-combustible materials.

Plenum, Supply. Forming part of the distribution system and attached directly to the outlet of the central heating or air conditioning unit (HAC unit), the supply plenum is a dispensing manifold to which two or more supply ducts are connected. It is considered duct; and all closure, in-
sulation and other requirements of duct shall apply to the supply plenum. Seal or Sealing. When used in relation to air distribution systems and mechanical equipment, a seal or sealing shall mean the use of any of the following closure systems: adhesives, gaskets, tape systems or combinations thereof, or continuous welds, to close joints, seams, and other openings in the surfaces of ductwork and air barriers through which air leakage would otherwise occur. No joint or opening from which a closure product is absent shall be considered sealed unless considered otherwise in specific cases identified by this Code. Closeness of fit between mated parts, alone, shall not be considered a seal.
