## ABSTRACT

Dose Reconstruction Using Computational Modeling of Handling a Particular

Arsenic-73/Arsenic-74 Source. (May 2010)

Alisha Marie Stallard, B.S., Baylor University

Chair of Advisory Committee: Dr. John W. Poston, Sr.

A special work evolution was performed at Los Alamos National Laboratory (LANL) with a particular  $^{73}\text{As}/^{74}\text{As}$  source but the worker's extremity dosimeter did not appear to provide appropriate dosimetric information for the tasks performed. This prompted a reconstruction of the dose to the worker's hands. The computer code MCNP was chosen to model the tasks that the worker performed to evaluate the potential nonuniform hand dose distribution. A model was constructed similar to the worker's hands to represent the performed handling tasks. The model included the thumb, index finger, middle finger, and the palm. The dose was calculated at the  $7 \text{ mg cm}^{-2}$  skin depth. To comply with the Code of Federal Regulations, 10 CFR 835, the  $100 \text{ cm}^2$  area that received the highest dose must be calculated. It could be determined if the dose received by the worker exceeded any regulatory limit. The computer code VARSKIN was also used to provide results to compare with those from MCNP where applicable.

The results from the MCNP calculations showed that the dose to the worker's hands did not exceed the regulatory limit of 0.5 Sv (50 rem). The equivalent nonuniform dose was 0.126 Sv (12.6 rem) to the right hand and 0.082 Sv (8.2 rem) to the left hand.

## DEDICATION

This thesis is dedicated to my loving and supportive parents, Peggy and Curtis. Without them, I would not be where I am today.

## ACKNOWLEDGMENTS

I am deeply grateful to my committee chair, Dr. Poston. His guidance, support, patience and encouragement have made the completion of this project possible. To my committee members, Dr. Ford and Dr. Walker, I owe great appreciation for their support throughout the course of this research.

I want to express great gratitude for Los Alamos National Laboratory for funding not only my thesis work, but for the great experience I have gained over the last three and a half years. Many thanks go to Jim Bland who voluntarily agreed to serve as my mentor. Jim offered me great insight and invaluable knowledge regarding my research as well as about health physics and working at LANL. Other LANL colleagues who have contributed their time and efforts with this research that I would like to thank include: Luiz Bertelli, Jeff Hoffman, Tom Waters, Alan Justus, Tom McLean, Milan Gadd, Dan Talley, Dick Olsher, David Seagraves, and RT Perry. Additional colleagues who have given me great support include: William Martinez, Shawna Eisele, John Bliss, Christine Pollard, and Murray Moore.

To Linda Morris, I am deeply grateful for her enthusiasm and introducing me to the exciting world of health physics. It was her support and guidance that led me to further my education at Texas A&M University and explore a career path at LANL.

To my parents, Peggy and Curtis, sister, Soraya, aunt, Wanda, and other family members and friends, I truly appreciate all of the unconditional love and support that they have given me throughout every endeavor.

## INTRODUCTION

Department of Energy (DOE) facilities, such as Los Alamos National Laboratory (LANL), must comply with the Code of Federal Regulations, 10 CFR 835, Occupational Radiation Protection. The radiation protection program (RPP) establishes controls to ensure radiological workers do not exceed regulatory limits of 0.5 Sv (50 rem) equivalent dose to the skin or any extremity within a year (10 CFR 835.202 2009). The goal of the RPP is to keep radiation doses to radiological workers as low as reasonably achievable (ALARA). Radiological workers are required to be monitored with external personal dosimeters if they are likely to receive an equivalent dose to the skin or any extremity of 0.05 Sv (5 rem) or more within a year (10 CFR 835.402 2009). If an individual is not monitored, if the dosimeter is worn incorrectly, or if an off-normal event occurs and no dosimeter data are available, a dose reconstruction must be performed. For nonuniform exposures affecting more than 100 cm<sup>2</sup> of skin surface, it is necessary to determine the 100 cm<sup>2</sup> receiving the maximum dose to comply with 10 CFR 835. A detailed evaluation of the distribution of dose within the affected area must be performed to fulfill these requirements. Such detailed external dose reconstructions are rarely done and the literature provides little guidance to follow when performing an external dose reconstruction.

MCNP is a radiation transport code that can be used for a variety of applications including radiation dosimetry (Pelowitz 2005). It can be used to simulate the transport

---

This thesis follows the style of Health Physics.

of photons, electrons, neutrons, or coupled photon/electron/neutron transport. Realistic conditions can be modeled with MCNP since the models are three-dimensional. MCNP can also be used to provide an evaluation of dose rates to specific areas of the geometry since it can be divided into small cells.

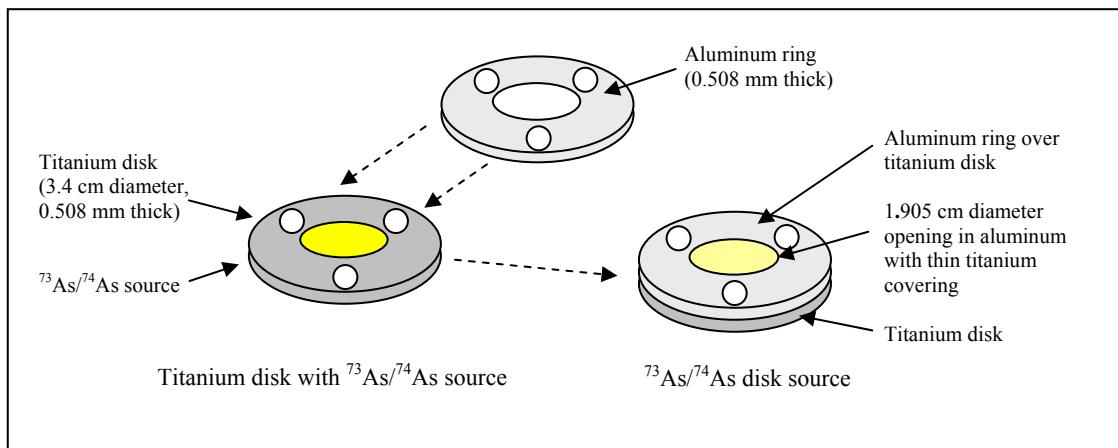

VARSKIN is a computer code that is used for calculating nonuniform doses to the skin. However, the code has some limitations that could impact its use for dose reconstructions, but it could prove useful for planning jobs involving the potential for receiving unwanted radiation dose. VARSKIN has not been tested for averaging doses over areas greater than  $10\text{ cm}^2$ , nor has it been tested for air gaps greater than 5 cm for beta doses (Durham 2006). Another major limitation is that complex geometries cannot be simulated. MCNP does not have the limitations that VARSKIN has and allows for the simulation of detailed geometries, thus making it a valuable tool for reconstructing uniform or nonuniform doses.

A nonroutine work evolution was performed at LANL with a particular  $^{73}\text{As}/^{74}\text{As}$  source disk. After the tasks were completed, it was determined that there was a large beta radiation field that was not accounted for during the planning of the work. Upon recognizing the potential for significant extremity exposures, LANL initiated an internal investigation which involved workers at two facilities. In each case, dose reconstruction was warranted due to inadequate application of extremity dosimetry. This research focused on the worker's dose reconstruction to the hands at one of the facilities.

## BACKGROUND

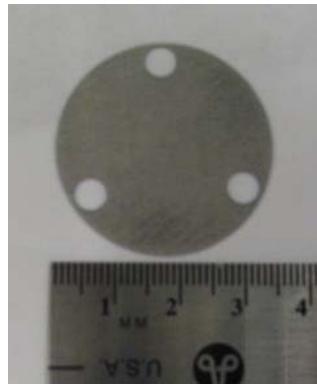

A special radioactive arsenic disk source was constructed in a hot cell and prepared for shipment. The preparation involved tasks where the worker used remote handling tools and handled the disk source directly. The first task involved moving the disk source with its stand from a train that transports materials into and out of a hot cell. The disk source with its stand was removed from the hot cell train using tongs and was placed onto a work surface. The worker smeared the disk source four times to check for any removable contamination. Lastly, the disk source was transferred into a shipping container.

The disk source was constructed in a hot cell with four components: 1) titanium base disk, 2)  $^{73}\text{As}/^{74}\text{As}$  source material, 3) aluminum ring, and 4) a thin titanium covering. The assembly of these components is illustrated in Fig. 1.

**Fig. 1.** Illustration of the titanium and aluminum disk source assembly.

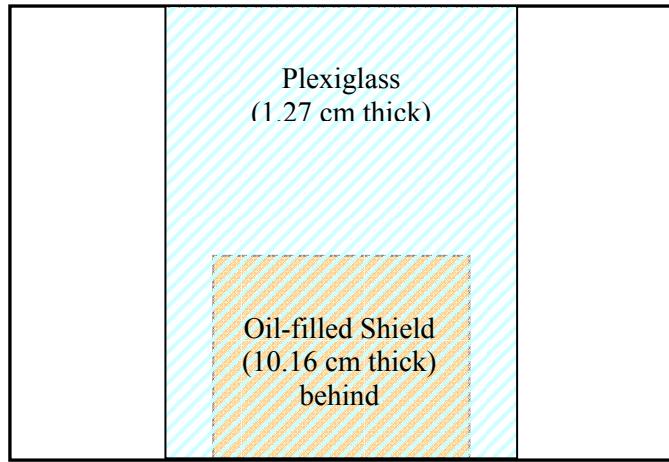

The disk source contained two radionuclides,  $^{73}\text{As}$  and  $^{74}\text{As}$ . The activity of each was 23.1 GBq (625 mCi) and 13.6 GBq (368 mCi), respectively. The source material was deposited onto the center of a titanium disk with a liquid dropper. As shown in Fig. 2, the titanium disk was 3.4 cm in diameter, 0.508 mm thick and had three holes equally spaced apart along the edge. A thin 2- $\mu\text{m}$  layer of titanium was used to cover the 1.905-cm diameter aperture of an aluminum ring that measured 3.4 cm in diameter, 0.508 mm thick, and also had three holes equally spaced apart along the edge. The aluminum ring with titanium window was adhered on top of the titanium disk with the three holes being aligned.

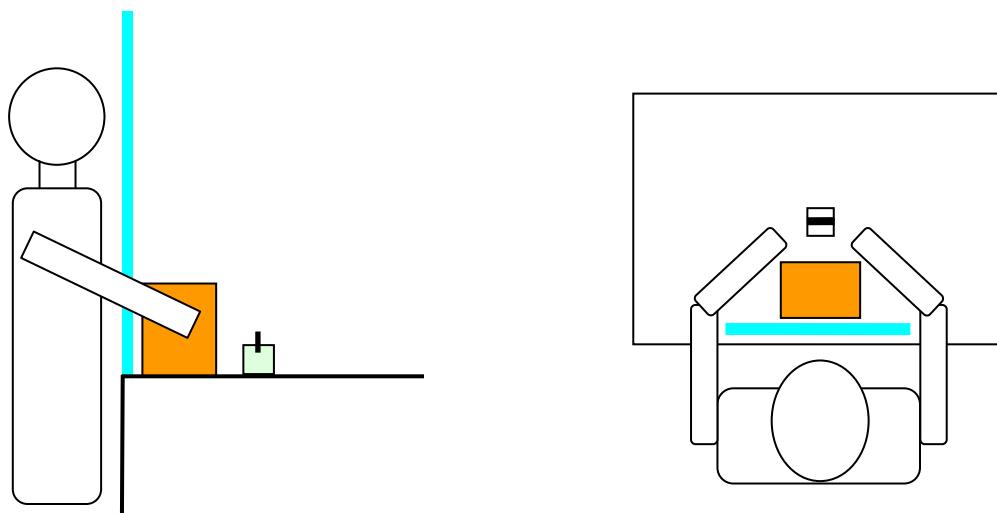

**Fig. 2.** Photograph of titanium disk measuring 3.4 cm in diameter.

Once the disk source was assembled in the hot cell, it was placed on a small train that transports materials into and out of the hot cell. The worker removed the disk source and its stand from the train with tongs and placed it on the workstation behind a 10.16-cm thick oil-filled shield. Between the oil-filled shield and the worker was a 1.27-

cm thick sheet of plexiglass, see Figs. 3 and 4. The worker's arms could reach around both sides of the shield to work with the disk source.

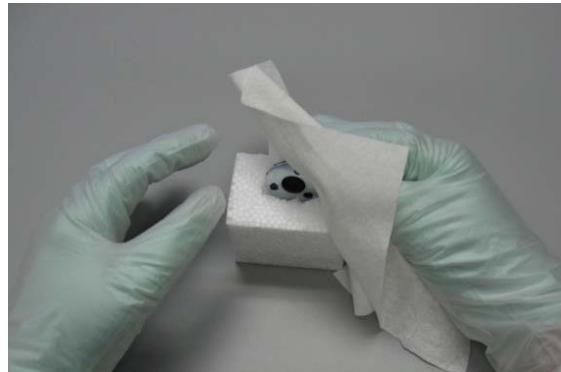

**Fig. 3.** Front view of the workstation.

**Fig. 4.** Side and top view of the workstation.

After the disk source was placed on the workstation surface, the worker performed the next task. Wearing one pair of nitrile gloves and three pairs of vinyl

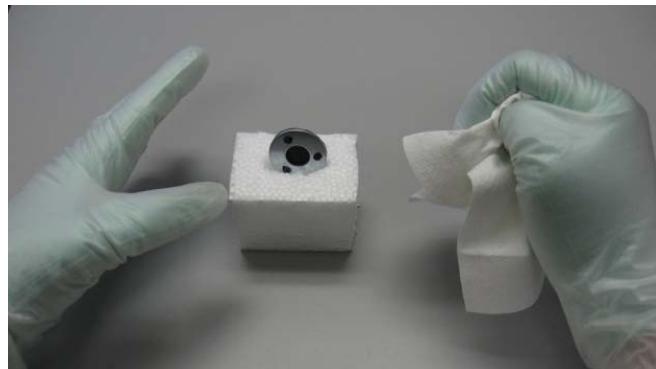

gloves, the worker reached around and behind the plexiglass and oil-filled shield where the disk source was located on a stand. The worker picked up the disk source with a wipe dampened with a decontamination solution, wiped it back and forth to decontaminate the outer surface, and placed the disk source back on the stand as simulated in Figs. 5, 6, and 7. With the wipe still in hand, the worker removed the outer pair of vinyl gloves with the wipe remaining inside the glove, as simulated in Figs. 8 and 9. This process was repeated two more times. When all of the vinyl gloves were removed, the worker donned another pair of vinyl gloves to perform the decontamination process a fourth time.

**Fig. 5.** Simulating picking up the disk source.

**Fig. 6.** Simulating smearing the disk source.

**Fig. 7.** After smearing, placing disk source back on the stand.

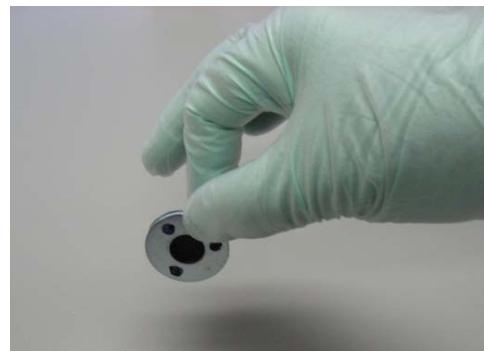

**Fig. 8.** Removing the outer vinyl gloves while keeping the wipe inside.

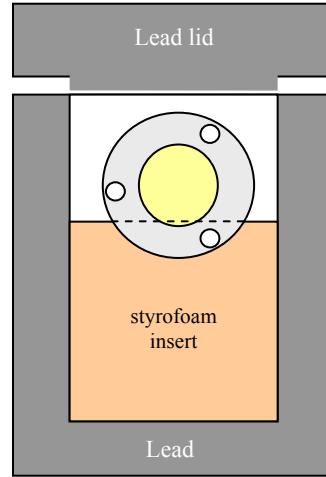

**Fig. 9.** Vinyl glove turned inside out with the wipe inside.

After the decontamination process was performed four times, the disk source had to be placed into a leaded shipping container. The worker picked up the disk source with the thumb and index finger as shown in Fig. 10. Inside the shipping container was a specially made styrofoam insert to hold the disk source safely and securely. Fig. 11 illustrates the composition of the leaded shipping container and how the disk source was placed inside.

**Fig. 10.** Holding the disk source with thumb and index finger.

**Fig. 11.** Illustration of the leaded shipping container.

Table 1 summarizes the duration for each task to be completed.

**Table 1.** Time required to complete each task.

Description of Task	Time (sec)
Removing disk source from hot cell train with tongs (1 Nitrile, 1 Vinyl)	3
Picking up disk source (1 Nitrile, 3 Vinyl)	1
Smearing disk source (1 Nitrile, 3 Vinyl)	2
Putting down disk source (1 Nitrile, 3 Vinyl)	1
Picking up disk source (1 Nitrile, 2 Vinyl)	1
Smearing disk source (1 Nitrile, 2 Vinyl)	2
Putting down disk source (1 Nitrile, 2 Vinyl)	1
Picking up disk source (1 Nitrile, 1 Vinyl)	1
Smearing disk source (1 Nitrile, 1 Vinyl)	2
Putting down disk source (1 Nitrile, 1 Vinyl)	1
Picking up disk source (1 Nitrile, 1 Vinyl)	1
Smearing disk source (1 Nitrile, 1 Vinyl)	2
Putting down disk source (1 Nitrile, 1 Vinyl)	1
Placing disk source into shipping container (1 Nitrile, 1 Vinyl)	5

In summary, the time required to move the disk source with the tongs was 3 seconds. The total contact time to smear the disk source four times was 16 seconds. It

took 5 seconds to place the disk source into the shipping container. Therefore, the overall process took 24 seconds. These three tasks were the basis for the dose reconstruction to the worker's hands.

## MATERIALS AND METHODS

### **MCNP**

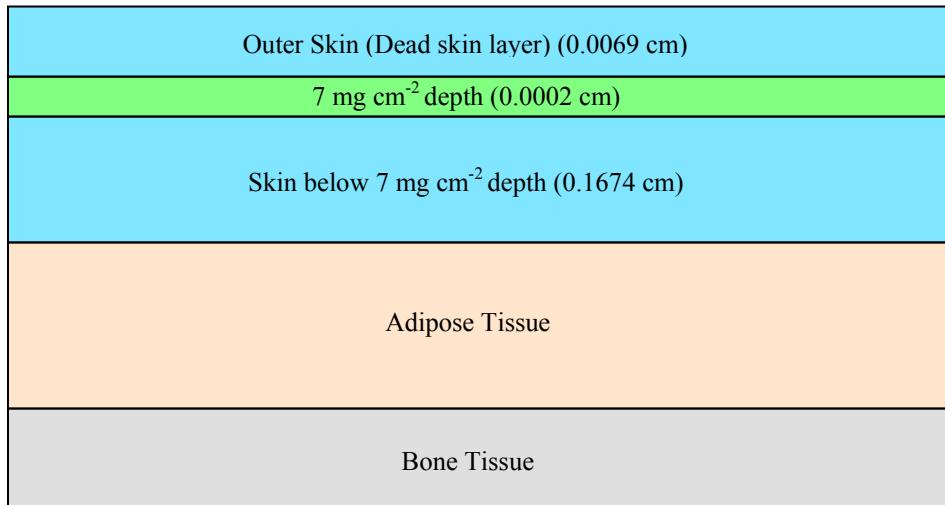

MCNP is a Monte Carlo radiation transport code that was developed at LANL. It is used for a variety of applications including radiation dosimetry, shielding design, and nuclear criticality safety (Pelowitz 2005). It can simulate the transport of photons, electrons, neutrons, or coupled photon/electron/neutron transport. MCNP follows every particle individually throughout every interaction until all of its energy is absorbed or until it leaves the cells that the user defines as being important. The output from the MCNP simulations can include a variety of tallies such as cell fluence, number of particles crossing a surface, or energy deposition.

With MCNP, the user can simulate detailed geometries because the user defines the three-dimensional geometry. The model can also be divided into many small cells so that tallies at specific areas can be evaluated. Depending on the complexity of the geometry, executing MCNP may take minutes or days due to the computational time required to follow several million or more particles. Because of the ability to model complex geometries with MCNP, it was chosen to be used as the primary tool for the dose reconstruction.

### **MCNP Geometry**

The composition and density of the materials used to model the hand were obtained from International Commission on Radiation Protection (ICRP) Publication 110, Adult Reference Computational Phantoms (ICRP 2009). The thickness of the skin

layers used throughout the hand model was obtained from ICRP Publication 89 and shown in Fig. 12 (ICRP 2002). The thickness of the outer skin, or dead skin layer, was modeled as 0.0069 cm so that the  $7 \text{ mg cm}^{-2}$  skin depth could be thick enough (0.0002 cm) to tally in MCNP. The approximate length and width of the worker's fingers and palm were also used to generate the hand model. The MCNP model simulated the actual positions of the worker's hands when the worker performed the tasks.

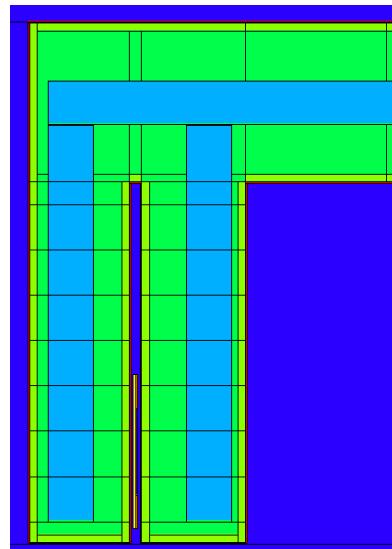

**Fig. 12.** Thickness of the modeled skin layers (not to scale).

Based on the worker's presentation of how the tasks were performed, the hand model included the index finger, thumb, middle finger, and the palm of the hand. A photograph simulating the general position of the hand is shown in Fig. 13. The side view of the MCNP hand model is shown in Fig. 14. The index finger is on the left and the thumb on the right. The palm is above the fingers and extending to the right. The front view of the MCNP hand model is shown in Fig. 15. The front of the palm

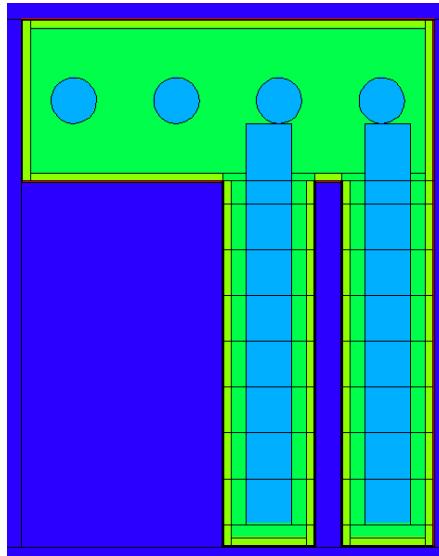

(knuckles) is shown on the top with the bones in the hand represented as cylinders. The index finger is on the right with the middle finger next to it.

**Fig. 13.** Photograph of general hand position.

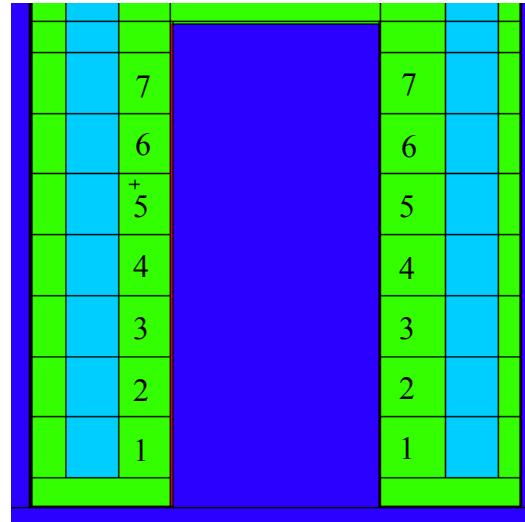

**Fig. 14.** MCNP side view of the index finger, thumb, and palm.

**Fig. 15.** MCNP front view of the index finger, middle finger and palm of the hand.

The fingers and thumb were modeled using several rectangular cells so that the localization of absorbed dose could be analyzed. The use of a rectangular structure for the fingers was chosen so that the absorbed dose could be determined on each side of the finger (front, back, inside, or outside), as well as along the length of the finger. The fingers and thumb were modeled as 2.0 cm thick, 2.3 cm wide and 8 cm long.

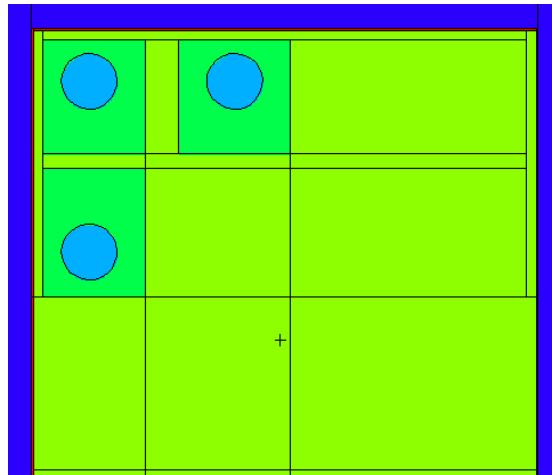

The length of the fingers was divided into eight sections above the finger tips. The first section was the first centimeter above the tip of the finger continuing up to section eight where the fingers meet the palm. The tip of the fingers and section eight were 0.5 cm each in length. Sections one through seven were each 1 cm long. The tip of each finger had four side cells and one end cell. Sections one through eight had four side cells each. The fingers and thumb were each divided into 138 cells at the  $7 \text{ mg cm}^{-2}$  depth. Fig. 16 shows the finger sections.

**Fig. 16.** MCNP model of the index finger and thumb sections.

The bones in the fingers, thumb, and palm were modeled as cylinders. The composition of the bones and adipose tissue were obtained from ICRP Publication 110 (ICRP 2009). Adipose tissue surrounded the bone and was under the skin layer. The bone and adipose tissue of each finger were divided into eight cells along the length, corresponding to sections of the fingers.

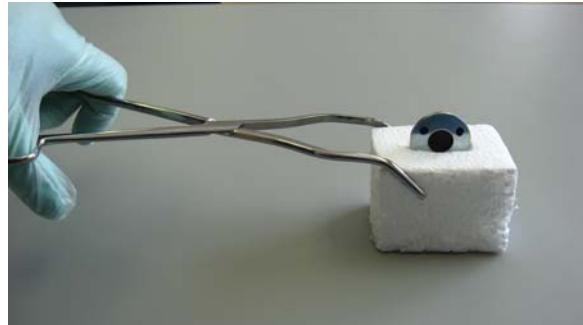

The palm was modeled as 8 cm wide, approximately 8 cm long, and 3.5 cm thick. Fig. 17 shows the right hand where the fingers meet the palm. The index and middle finger are across the top with the thumb just below the index finger.

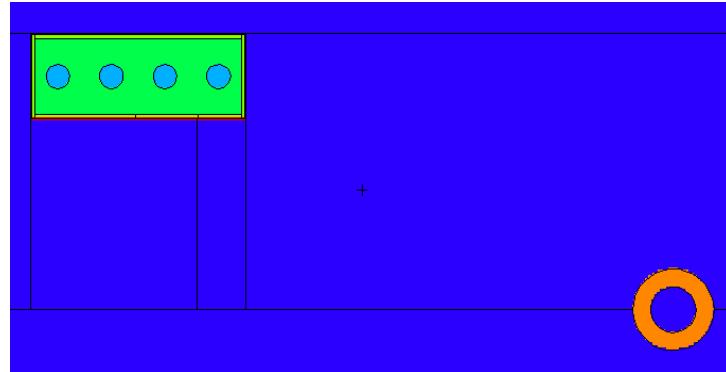

**Fig. 17.** MCNP model of palm of hand.

### MCNP Models of Tasks Performed

The disk source along with the stand was removed from the hot cell train using 20-cm long tongs and placed behind the plexiglass and thick oil-filled shielded workstation. A photograph simulating the worker using tongs to pick up the disk source (with disk source opening away from the hand) and stand is shown in Fig. 18. The side view of the MCNP model is illustrated in Fig. 19. This illustration only shows the palm of the hand and the aluminum ring of the disk source. The index finger and thumb would be located between the two vertical lines below the right side of the palm if a three-dimensional model could have been shown. A sample of the MCNP input file for using tongs is found in Appendix A.1.

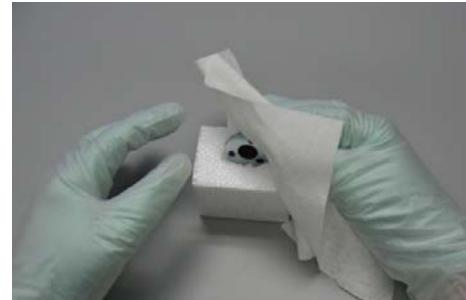

**Fig. 18.** Simulation of the disk source and stand picked up with tongs.

**Fig. 19.** MCNP side view of picking up the disk source and stand with tongs.

Once the disk source and stand were placed on the workstation, the decontamination process began. The worker picked up the disk source from the stand with the wipe as simulated in Fig. 20. The worker smeared the disk source with a wipe dampened with a decontamination solution to check for removable  $^{73}\text{As}$  and  $^{74}\text{As}$  material.

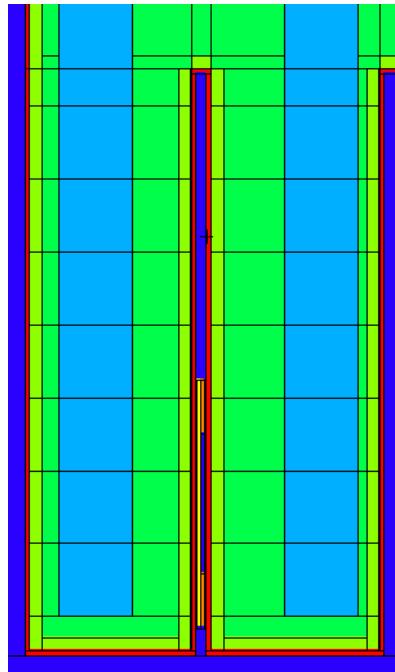

**Fig. 20.** Picking up the disk source with wipe for smearing.

The wipe was folded over the front of the disk source and rubbed back and forth on the front and back surfaces. Portions of the worker's thumbs were directly over the disk source opening and portions of the index and middle finger were directly under the center of the back titanium disk. Fig. 21 simulates the worker smearing the disk source. The MCNP model of this task is illustrated in Fig. 22. Section two of the thumb is directly over the disk source opening whereas sections one and three are partially over the disk source opening. This model provides absorbed dose rate estimations as the thumb moves across the  $^{73}\text{As}/^{74}\text{As}$  disk source.

**Fig. 21.** Simulation of smearing the disk source for removable  $^{73}\text{As}/^{74}\text{As}$  material.

**Fig. 22.** MCNP model of smearing the disk source.

Each time the disk source was smeared, a pair of vinyl gloves was removed with the wipe inside the vinyl glove. An MCNP model was developed to estimate the absorbed dose rates to the thumb, index finger, middle finger, and palm for the following conditions:

- 1) Three pairs of vinyl gloves and one pair of nitrile gloves.
- 2) Two pairs of vinyl gloves and one pair of nitrile gloves.
- 3) One pair of vinyl gloves and one pair of nitrile gloves.

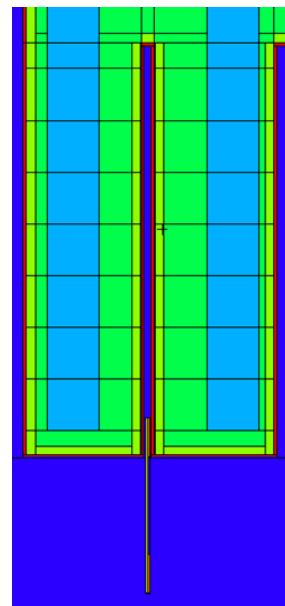

A sample of the MCNP input file for smearing the disk source is found in Appendix A.2.

After the smearing process, the worker placed the disk source into a leaded shipping container for transport. The worker picked up the disk source with the thumb touching the aluminum ring just above the disk source opening and the index finger on

the back surface of the titanium base disk. The disk source opening was towards the thumb direction as shown in Fig. 23. The MCNP model of this task is illustrated in Fig. 24. A sample of the MCNP input file for holding the disk source is found in Appendix A.3

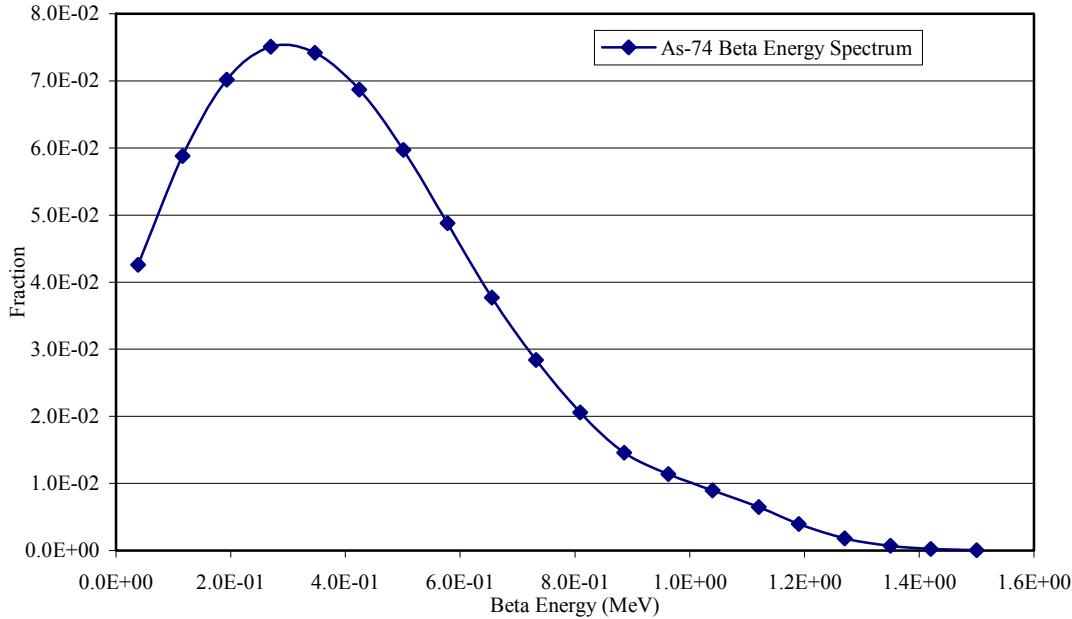

**Fig. 23.** Picking up the disk source.

**Fig. 24.** MCNP model of picking up the disk source to place into the leaded shipping container.

## MCNP Source Term

The two radionuclides that made up the source term were  $^{73}\text{As}$  and  $^{74}\text{As}$ . The activities were 23.1 GBq (625 mCi) and 13.6 GBq (368 mCi), respectively. As-73 decays by electron capture and emits several photons. As-74 decays by electron capture (~37%), positron (~29%) and beta minus (~34%). Depending on the reference, the percent of electron capture, positron and beta minus will vary. The percentages were obtained from data by Eckerman, Burrows, Lederer, and the National Nuclear Data Center (Lederer 1978, Burrows 1988, Eckerman 1994, NNDC 2009). There were three source term calculations for each MCNP model: 1)  $^{73}\text{As}$  photons; 2)  $^{74}\text{As}$  photons; and 3)  $^{74}\text{As}$  electron (beta) spectrum. A beta spectrum was used in MCNP for  $^{74}\text{As}$  which combined the positron and beta minus as a beta minus spectrum, see Fig. 25. The beta spectrum was constructed from data published by Eckerman (Eckerman 1994). The 0.511 MeV annihilation photons from positrons were included in the  $^{74}\text{As}$  photon source term.

**Fig. 25.** Beta spectrum used in MCNP models for  $^{74}\text{As}$  (Eckerman et al., 1994).

The radiological properties of  $^{73}\text{As}$  and  $^{74}\text{As}$  are summarized in Table 2.

**Table 2.** Radiological properties of  $^{73}\text{As}$  and  $^{74}\text{As}$ .

Radionuclide	Half-Life	Decay Mode	Threshold Energy
		EC (100%)	
As-73	80.3 d	$\gamma$	9.87 keV (90.3%) 10.98 keV (11.5%) 53.4 keV (10.3%)
		EC (37%)	336 keV (0.016%) 944.6 keV (26.1%) 1540.5 keV (3%)
		$\beta^+$ (29%)	83.2 keV (0.02%) 718.0 keV (15.4%) 1352.8 keV (19%)
		$\beta^-$ (34%)	9.87 keV (15.1%) 10.98 keV (1.9%) 511 keV (58%)
As-74	17.78 d	$\gamma$ (combined $\beta^+$ , $\beta^-$ and EC)	595.8 keV (59%) 608.4 keV (5.5%) 634.8 keV (15.4%) 1204.3 keV (2.8%)

The source terms used for  $^{73}\text{As}$  photons,  $^{74}\text{As}$  photons, and  $^{74}\text{As}$  betas are shown in Figs. 26, 27 and 28, respectively.

## MCNP Tallies

To determine the dose to the hands, an energy deposition tally, or “F6” tally, was used. This tally accumulates results in terms of energy deposited per unit mass in units of MeV g<sup>-1</sup> for each tally cell. A tally multiplier was used to convert the energy deposition results into a dose rate. Equation 1 was the tally multiplier used to attain a dose rate in Gy s<sup>-1</sup> for <sup>73</sup>As photons:

$$\frac{\text{X tally}}{\text{source particle}} \cdot \frac{2.3125 \times 10^{10} \text{ dis}}{\text{s}} \cdot \frac{1.1211 \text{ source particles}}{\text{dis}} \cdot \frac{1 \text{ Gy}}{6.242 \times 10^9 \frac{\text{MeV}}{\text{g}}} \quad (1)$$

$$= \frac{4.1534 \text{ Gy}}{\text{s}} \text{ per } 6.242 \times 10^9 \frac{\text{MeV}}{\text{g}} 2.3125 \times 10^{10} \text{ Bq of } {}^{73}\text{As photon.}$$

The constant of 1 Gy = 6.242 X 10<sup>9</sup> MeV g<sup>-1</sup> is explained with Equation 2 using constants found in the Handbook of Health Physics and Radiological Health (Shleien et al. 1998).

$$\frac{6.242 \times 10^{12} \text{ MeV}}{\text{J}} \times \frac{\text{J}}{10^7 \text{ ergs}} \times \frac{10^4 \text{ ergs}}{\text{g} \cdot \text{Gy}} = 6.242 \times 10^9 \frac{\text{MeV}}{\text{g} \cdot \text{Gy}}. \quad (2)$$

$$\therefore 1 \text{ Gy} = 6.242 \times 10^9 \frac{\text{MeV}}{\text{g}}$$

Equation 3 was the tally multiplier used to attain a dose rate in Gy s<sup>-1</sup> for <sup>74</sup>As photons:

$$\frac{\text{X tally}}{\text{source particle}} \cdot \frac{1.3616 \times 10^{10} \text{ dis}}{\text{s}} \cdot \frac{1.3615 \text{ source particles}}{\text{dis}} \cdot \frac{1 \text{ Gy}}{6.242 \times 10^9 \frac{\text{MeV}}{\text{g}}} \quad (3)$$

$$= \frac{2.9699 \text{ Gy}}{\text{s}} \text{ per } 6.242 \times 10^9 \frac{\text{MeV}}{\text{g}} 1.3616 \times 10^{10} \text{ Bq of } {}^{74}\text{As photon.}$$

Equation 4 was the tally multiplier used to attain a dose rate in Gy s<sup>-1</sup> for <sup>74</sup>As betas:

$$\frac{\text{X tally}}{\text{source particle}} \cdot \frac{1.3616 \times 10^{10} \text{ dis}}{\text{s}} \cdot \frac{0.633022 \text{ source particles}}{\text{dis}} \cdot \frac{1 \text{ Gy}}{6.242 \times 10^9 \frac{\text{MeV}}{\text{g}}} \quad (4)$$

$$= \frac{1.3808 \text{ Gy}}{\text{s}} \text{ per } 6.242 \times 10^9 \frac{\text{MeV}}{\text{g}} 1.3616 \times 10^{10} \text{ Bq of } {}^{74}\text{As betas.}$$

A total of 47 tallies were calculated using MCNP. A listing of these tallies is shown in Table 3. Some tallies included only one cell; however, many of the tallies contained a combination of cells. For example, tally number six (7 mg cm<sup>-2</sup> inner index) included the following cells: 135, 163, 189, 215, 241, 267, 293, 319, and 345. These cells incorporate the inner side of the tip and sections one through eight of the inner side of the index finger.

**Table 3.** MCNP estimated absorbed dose rate tallies.

Tally No.	Description of Estimated Absorbed Dose Rate Tally	Tally No.	Description of Estimated Absorbed Dose Rate Tally
6	$7 \text{ mg cm}^{-2}$ Inner Index	246	Skin Below Inner Middle Finger
16	$7 \text{ mg cm}^{-2}$ Inner Thumb	256	Outer Skin Tip of Fingers

## **VARSKIN**

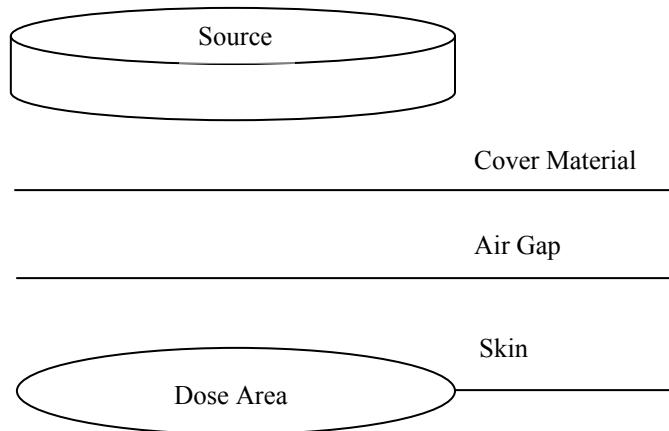

VARSKIN is a computer program that is used to calculate nonuniform doses to the skin from contamination, including hot particles. The code is useful because it determines photon dose and beta dose at the  $7 \text{ mg cm}^{-2}$  skin depth. This computer program was originally developed for use by the Nuclear Regulatory Commission (NRC); however, its use has become much more widespread in the nuclear industry.

VARSKIN is a point kernel code. The dose is determined at many dose points and then averaged to obtain an overall dose. A major advantage to using the code is that the computational time is almost instantaneous. Even though the code was developed for skin dose from skin contamination, it can also be used to estimate shallow dose from an external source within 5 cm from the skin surface. The user can also specify the dose to be averaged over an area up to  $10 \text{ cm}^2$  (Durham 2006).

There are several limitations of VARSKIN. Doses averaged over more than  $10 \text{ cm}^2$  may result in errors. Users are alerted that if the distance from the source to the skin is greater than 5 cm, errors may result. Furthermore, the geometry parameters are very simple and cannot accommodate complex models. The code allows the user to input a cover material over the source and an air gap between the cover material and skin. Because of these limitations, this code could not be used for a dose reconstruction of this complexity. However, it could be useful in planning purposes, if one handles a beta-emitting source.

## **VARSKIN Model**

The VARSKIN model was used to estimate the beta dose from the smearing tasks. The model was constructed to represent the highest exposed thumb section determined from the MCNP model (cell number 202). The disk source was modeled as a disk source with a diameter of 1.91 cm. The irradiation area was  $2 \text{ cm}^2$  and the irradiation time was one second. Three models were set up for one nitrile/one vinyl glove, one nitrile/two vinyl gloves, and one nitrile/three vinyl gloves. In VARSKIN, gloves are considered a cover material. The thickness of each glove measured 0.015 cm with a density of  $1.65 \text{ g cm}^{-3}$ . VARSKIN was used only to calculate the dose rate from  $^{74}\text{As}$  beta particles. An illustration of the VARSKIN model is shown in Fig. 29.

**Fig. 29.** Illustration of VARSKIN model.

## RESULTS

### **MCNP**

The absorbed dose rate was tallied for 300 cells. These cells included the outer skin, the  $7 \text{ mg cm}^{-2}$  skin depth, the skin below the  $7 \text{ mg cm}^{-2}$  depth, and the bones. This research focused on 127 of the 300 cell tallies which were at the  $7 \text{ mg cm}^{-2}$  skin depth. The  $^{73}\text{As}$  photon,  $^{74}\text{As}$  photon, and  $^{74}\text{As}$  beta dose rates were summed which resulted in the total cell dose rate for the 127 cells of interest for each task. Appendix B shows the results for the  $7 \text{ mg cm}^{-2}$  skin depth tally cells which include the area of each cell, the dose rate from each radionuclide and the associated percent error for all tasks. The time required for each task was multiplied by the cell dose rate, which resulted in absorbed dose for each  $7 \text{ mg cm}^{-2}$  skin depth cell. Once the absorbed dose was calculated for each tally cell, the  $100 \text{ cm}^2$  area that received the highest dose was determined to comply with 10 CFR 835 requirements. The dose for each cell was sorted from the highest to lowest dose. The dose was multiplied by the fraction of the cell area to the total  $100 \text{ cm}^2$  area. The absorbed doses were summed for all tasks over the  $100 \text{ cm}^2$  area receiving the highest dose to estimate the worker's nonuniform dose.

The dose rate results for moving the disk source with tongs are found in Appendix B.1. The task of moving the disk source with the tongs took approximately three seconds. This was completed with the worker's right hand while wearing one nitrile and one vinyl glove. Considering only the tong task, Appendix C.1 shows the cells contributing to highest dose rate of the  $100 \text{ cm}^2$  area. The cells that received the highest dose rate were the front face of the thumb, palm, and index finger. The percent

contribution to the total dose rate for this task from photons and beta particles is shown in Appendix D.1 for the cells contributing to the highest  $100\text{ cm}^2$  area. The  $^{74}\text{As}$  beta radiation contributed 90%, the  $^{74}\text{As}$  photons contributed 9%, and the  $^{73}\text{As}$  photons contributed 1% of the total dose rate for this task.

The smearing task incorporated two separate tasks. The disk source was picked up from the stand, smeared, and placed back on the stand. The worker used both hands to smear the disk source. The smearing task alone took approximately one second with the right hand and one second with the left hand. The worker used the right hand to pick up and put down the disk source which took a total of two seconds. The smearing task results for three, two, and one vinyl glove are shown in Appendix B.2 through B.4. The holding of the disk source results for the various number of vinyl gloves are shown in Appendix B.5 through B.7.

The dose rate from the smearing task was concentrated mostly over the inner sections of the thumb, index finger, and middle finger. Considering only the smearing task, Appendix C.2 through C.4 shows the cells contributing to highest dose rate of the  $100\text{ cm}^2$  area for the various number of vinyl gloves. The percent contribution to the total dose rate from photons and beta particles is shown in Appendix D.2 through D.4 for the various number of vinyl gloves. Depending on the number of vinyl gloves worn, the  $^{74}\text{As}$  beta radiation contributed 73 – 85%, the  $^{74}\text{As}$  photons contributed 11 – 26%, and the  $^{73}\text{As}$  photons contributed 1 – 2% of the total dose rate for the smearing task.

The cells that received the highest dose rates for holding the disk source task before and after smearing were the tips of the fingers, and the lower sections of the

thumb, index finger, and middle finger. Considering only the holding task, Appendix C.5 through C.7 shows the cells contributing to highest dose rate of the 100 cm<sup>2</sup> area for the various number of vinyl gloves. The percent contribution to the total dose rate from photons and beta particles is shown in Appendix D.5 through D.7 for the various number of vinyl gloves. Depending on the number of vinyl gloves worn, the contribution of the <sup>74</sup>As beta radiation was 61 – 77%, the <sup>74</sup>As photons contributed 22 – 37%, and the <sup>73</sup>As photons contributed 1 – 2% of the total dose rate for holding the disk source task.

The task of placing the disk source into the shipping container was performed with the worker's right hand while wearing one nitrile and one vinyl glove. This task took approximately five seconds. The results in Appendix B.7 can also be used for this task. Considering only this task, the cells contributing to highest dose rate of the 100 cm<sup>2</sup> area are shown in Appendix C.7. The percent contribution of photons and beta particles is shown in Appendix D.7. The contribution of the <sup>74</sup>As beta radiation was 77%, the <sup>74</sup>As photons contributed 22%, and the <sup>73</sup>As photons contributed 1% of the total dose rate for this task.

The tasks to determine the nonuniform skin dose to the right and left hand are summarized in Table 4. To determine the nonuniform skin dose to the cells contributing to the 100 cm<sup>2</sup> receiving the maximum dose to the right hand, Equation 5 was used. The 100 cm<sup>2</sup> area which received the maximum dose was composed of 50 cells for the right hand and is summarized in Appendix E.1. The actual area of the 50 cells used for the nonuniform dose determination was 100.8282 cm<sup>2</sup>.

**Table 4.** Summary of tasks used to determine the nonuniform dose to the skin.

Right Hand Task Descriptions	Left Hand Task Descriptions
Using tongs to move disk source	
Smearing the disk source 4 times: <ul style="list-style-type: none"> <li>• 1 Nitrile, 3 Vinyl Holding/Smearing</li> <li>• 1 Nitrile, 2 Vinyl Holding/Smearing</li> <li>• 1 Nitrile, 1 Vinyl Holding/Smearing</li> <li>• 1 Nitrile, 1 Vinyl Holding/Smearing</li> </ul>	Smearing the disk source 4 times: <ul style="list-style-type: none"> <li>• 1 Nitrile, 3 Vinyl Smearing</li> <li>• 1 Nitrile, 2 Vinyl Smearing</li> <li>• 1 Nitrile, 1 Vinyl Smearing</li> <li>• 1 Nitrile, 1 Vinyl Smearing</li> </ul>
Placing disk source into shipping container	

$$\text{Estimated Nonuniform Skin Dose} = \sum \left[ \text{Cell Dose(Gy)} \times \left( \frac{\text{Cell Area(cm}^2\text{)}}{100.8282 \text{ cm}^2} \right) \right]. \quad (5)$$

To determine the nonuniform skin dose to the cells contributing to the  $100 \text{ cm}^2$  receiving the maximum dose to the left hand, Equation 6 was used. The  $100 \text{ cm}^2$  area which received the maximum dose was composed of 49 cells for the left hand and is summarized in Appendix E.2. The actual area of the 49 cells used for the nonuniform dose determination was  $100.6482 \text{ cm}^2$ .

$$\text{Estimated Nonuniform Skin Dose} = \sum \left[ \text{Cell Dose(Gy)} \times \left( \frac{\text{Cell Area(cm}^2\text{)}}{100.6482 \text{ cm}^2} \right) \right]. \quad (6)$$

The calculated nonuniform skin dose for the right hand is  $0.126 \text{ Gy} \pm 0.0008 (1\sigma)$ . The calculated nonuniform skin dose for the left hand is  $0.082 \text{ Gy} \pm 0.0005 (1\sigma)$ .

The absorbed dose can be converted to sieverts (Sv) by multiplying by the radiation weighting factor for betas and gammas, which is one. Therefore the nonuniform equivalent dose is 0.126 Sv (12.6 rem) to the right hand and 0.082 Sv (8.2 rem) to the left hand.

## **VARSKIN**

Due to the limitations of VARSKIN, the only task that could be evaluated using the VARSKIN code and compared to MCNP was the smearing task. The VARSKIN model was set up similarly to the highest exposed thumb section from the MCNP model (cell number 202). The results from the VARSKIN calculations and comparisons with MCNP (cell number 202) results are shown in Table 5.

**Table 5.** Beta dose results from VARSKIN compared with results from MCNP.

Smearing Disk Source	VARSKIN	MCNP
1 Nitrile, 3 Vinyl	241 mGy s <sup>-1</sup>	300 mGy s <sup>-1</sup>
1 Nitrile, 2 Vinyl	357 mGy s <sup>-1</sup>	425 mGy s <sup>-1</sup>
1 Nitrile, 1 Vinyl	509 mGy s <sup>-1</sup>	614 mGy s <sup>-1</sup>

The VARSKIN results are in close agreement with the MCNP results. Because of the inability to model complex geometries in VARSKIN, backscatter from the titanium base disk could not be estimated. Therefore, the VARSKIN results are lower than the results from MCNP.

## CONCLUSIONS

The results from MCNP showed that the nonuniform dose to the worker's skin did not exceed the regulatory limit of 0.5 Sv (50 rem). The nonuniform equivalent dose was 0.126 Sv (12.6 rem) to the worker's right hand and 0.082 Sv (8.2 rem) to the worker's left hand.

Comparing the results from each task showed that using remote handling tools could reduce the dose rate to the worker's hands since most of the contribution was from beta radiation. The dose rate from the smearing task could have been reduced by as much as 240 times by using tongs if the duration of the task remained the same. If holding the disk was done with tongs instead of the worker's fingers, the dose rate could have been reduced by as much as 19 times if the duration of the task remained the same. The dose rate could have been further reduced if a plastic shield had been attached at the hinge of the tongs to block the beta radiation from reaching the worker's hands.

Health physicists must evaluate any new process to determine the best way a radiation source should be handled to ensure that worker's doses are kept ALARA. The results of this research demonstrated that VARSKIN can be useful when planning work that involves beta-emitting radionuclides to obtain a quick estimate of the dose rate on contact and up to 5 cm from the skin surface. MCNP was shown to be a good tool for performing a complex dose reconstruction. Even though the regulatory limit was not exceeded, this event will be used as a learning experience so that a situation such as this one can be avoided in the future.
